

### The Fundamental Units of Life

- All organisms are made of cells
- The cell is the simplest collection of matter that can live
- Cell structure is correlated to cellular function
- All cells are <u>related</u> by their descent from earlier cells

# To study cells, biologists use microscopes and the tools of biochemistry

- Though usually too small to be seen by the unaided eye, cells can be complex
- Microscopy:
- Scientists use microscopes to visualize cells too small to see with the naked eye

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

### microscope

 In a light microscope (LM), visible light passes through a specimen and then through glass lenses, which magnify the image

- The quality of an image depends on
  - Magnification, the <u>ratio</u> of an object's image size to its real size
  - \_ Resolution, the measure of the clarity of the image, or the minimum distance of two distinguishable points

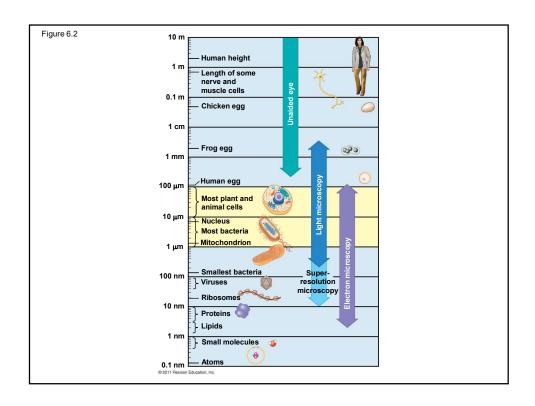

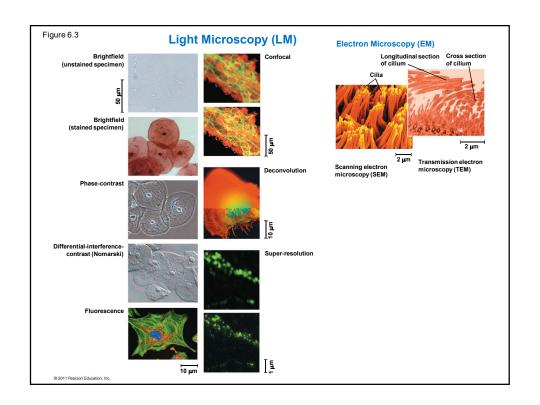

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummin

#### The quality of an image depends on

-Contrast, visible differences in parts of the sample

- LMs can magnify effectively to about 1,000 times the size of the actual specimen
- Various techniques enhance contrast and enable cell components to be <u>stained</u> or labeled

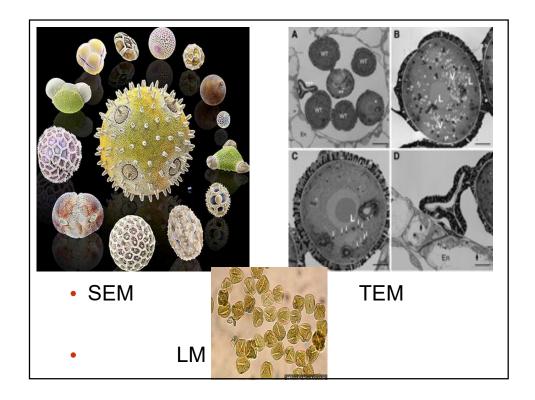

© 2011 Pearson Education, Inc

Most subcellular structures, including organelles (membrane-enclosed compartments), are too small to be resolved by an LM

### **Electron microscopes**

- Two basic types of electron microscopes (EMs) are used to study subcellular structures
- Scanning electron microscopes (SEMs) focus a beam of electrons onto the <u>surface of a specimen</u>, providing images that look <u>3-D</u>

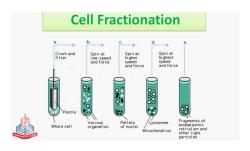

- Transmission electron microscopes (TEMs) focus a beam of electrons through a specimen
- TEMs are used mainly to study the internal structure of cells

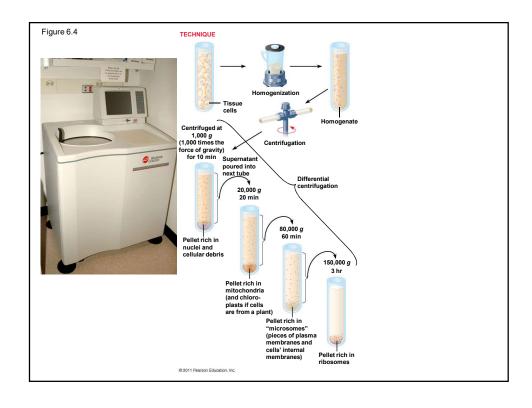

### **Cell Fractionation**

- Cell fractionation takes cells apart and separates the major organelles from one another
- <u>Ultracentrifuges</u> fractionate cells into their component parts

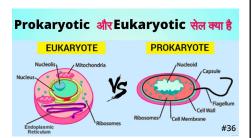

- Cell fractionation enables scientists to determine the functions of organelles
- Biochemistry and cytology help correlate cell function with structure

# **Eukaryotic cells** have <u>internal</u> membranes that compartmentalize their functions

- The basic structural and functional unit of every organism is one of two types of cells:
- •
- -prokaryotic o
- -eukaryotic

- Only organisms of the domains Bacteria and Archaea consist of prokaryotic cells
- Protists, fungi, animals, and plants <u>all</u> consist of eukaryotic cells

#### Prokaryotic vs. Eukaryotic Cells

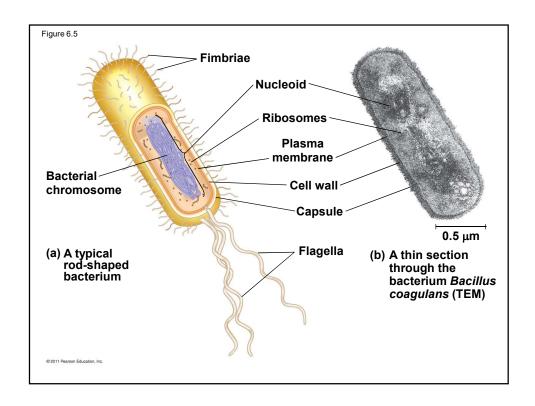

### **Basic features of all cells:**

مهم للغاية

- -Plasma membrane
- -Semifluid substance called cytosol
- -Chromosomes (carry genes)
- Ribosomes (make proteins)

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

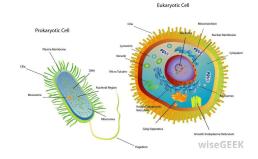

- Prokaryotic cells are characterized by having
  - -No nucleus
  - DNA in an unbound region called the nucleoid
  - No membrane-bound organelles
  - Cytoplasm bound by the plasma membrane

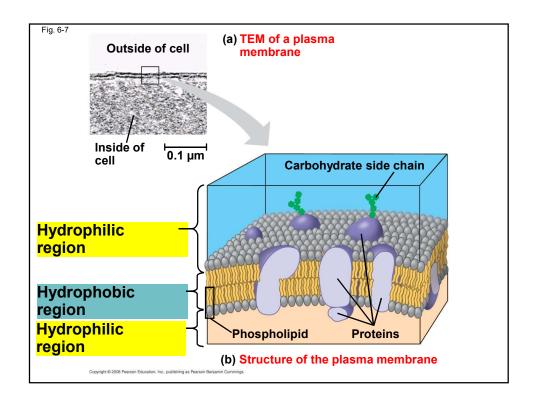

- Eukaryotic cells are characterized by having
  - -DNA in a nucleus that is bounded by a membranous nuclear envelope
  - -Membrane-bound organelles
  - Cytoplasm in the region <u>between</u> the plasma membrane and nucleus

 Eukaryotic cells are generally <u>much</u> <u>larger</u> than prokaryotic cells

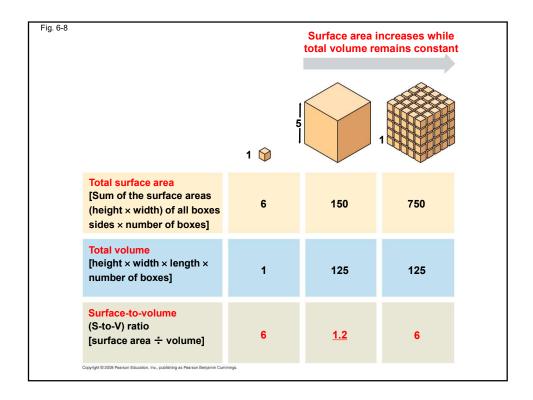

- The plasma membrane is a <u>Selective</u> barrier that <u>allows sufficient passage</u> of oxygen, nutrients, and waste to service the volume of every cell
- The general structure of a biological membrane is a double layer of phospholipids

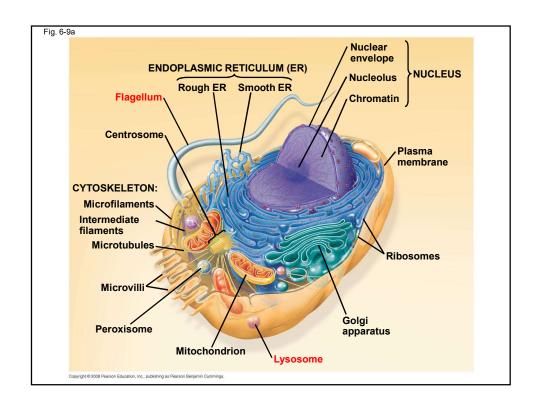

## Cell size

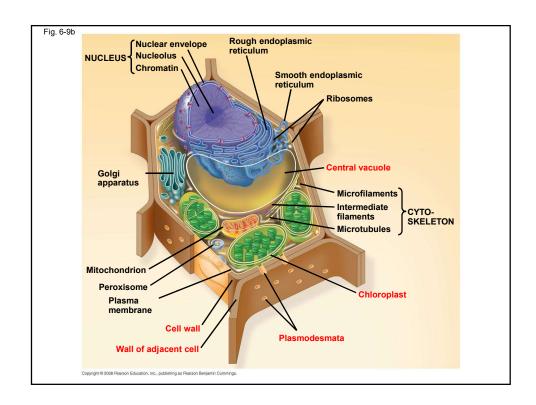

- Metabolic requirements set upper limits on the size of cells
- The surface area to volume ratio of a cell is critical
- Small cells have a greater surface area relative to volume

# A Panoramic View of the Eukaryotic Cell

- A eukaryotic cell has internal membranes that partition the cell into organelles
- Plant and animal cells have most of the same organelles

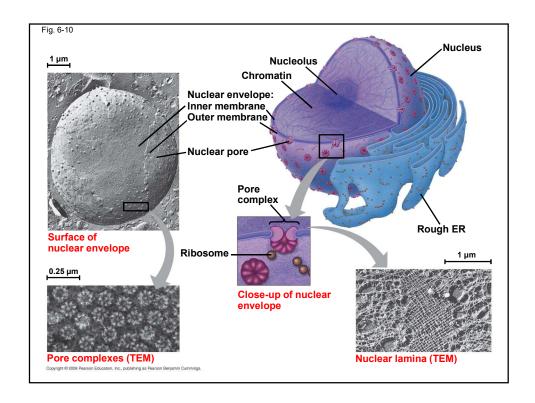

The eukaryotic cell's genetic instructions are <u>housed</u> in the nucleus and carried out by the ribosomes

- The nucleus contains most of the DNA in a eukaryotic cell
- Ribosomes use the information from the DNA to make proteins

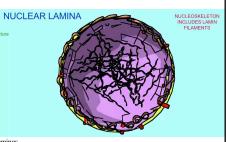

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

#### The Nucleus: Information Central

- The nucleus is usually the most conspicuous organelle
- The nuclear envelope encloses the nucleus
- The nuclear membrane is a double membrane; each membrane consists of a lipid bilayer

- Pores regulate the entry and exit of molecules from the nucleus
- The shape of the nucleus is maintained by the <u>nuclear lamina</u>, which is composed of protein

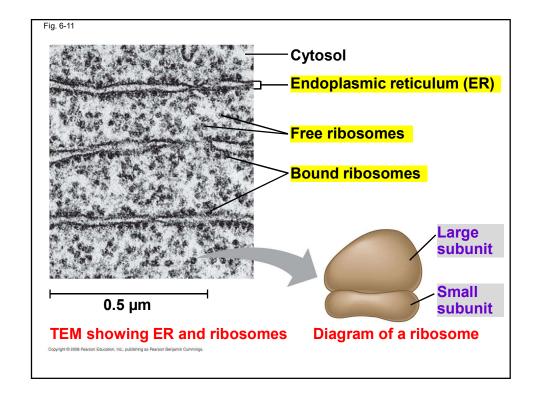

- In the nucleus, DNA is organized into discrete units called chromosomes.
- Each chromosome is composed of a <u>single</u> DNA molecule <u>associated</u> with <u>proteins</u>
- DNA and proteins form genetic material called chromatin.

- Chromatin <u>condenses</u> to form discrete <u>chromosomes</u> as a cell prepares to divide.
- The <u>nucleolus</u> is located within the nucleus and is the <u>site of</u> ribosomal RNA (rRNA) synthesis

### **Ribosomes:** Protein Factories

- Ribosomes are particles made of ribosomal RNA and protein
- Ribosomes carry out protein synthesis in two locations:
  - In the cytosol (**free** ribosomes)
  - On the outside of the endoplasmic reticulum or the nuclear envelope (bound ribosomes)

# The endomembrane system regulates protein traffic and performs metabolic functions in the cell

- Components of the system:
  - Nuclear envelope
  - -Endoplasmic reticulum
  - Golgi apparatus
  - Lysosomes
  - Vacuoles
  - Plasma membrane

 These components are <u>either</u> <u>continuous</u> or <u>connected via transfer</u> by <u>Vesicles</u>

# The Endoplasmic Reticulum: Biosynthetic Factory

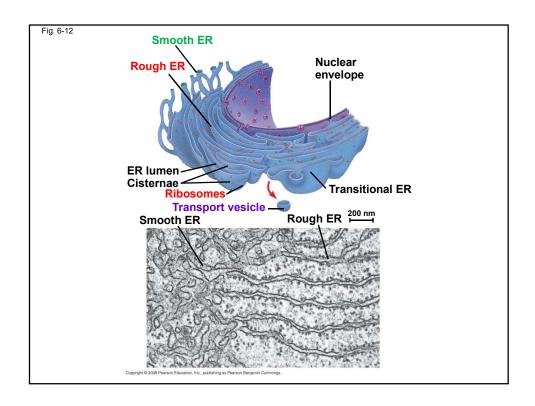

- The endoplasmic reticulum (ER)
   accounts for more than half
   of the total membrane in
   many eukaryotic cells
- The <u>ER membrane</u> is continuous with the <u>nuclear envelope</u>

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

 There are two distinct regions of ER:

-Smooth ER that lacks ribosomes

-Rough ER that have ribosomes studding its surface

# Functions of Smooth ER

- The smooth ER
  - -Synthesizes lipids
  - -Metabolizes carbohydrates
  - -Detoxifies poison
  - -Stores calcium

### Functions of Rough ER

- The rough ER
  - Has bound ribosomes, which secrete

# glycoproteins

(<u>proteins covalently bonded to carbohydrates</u>)

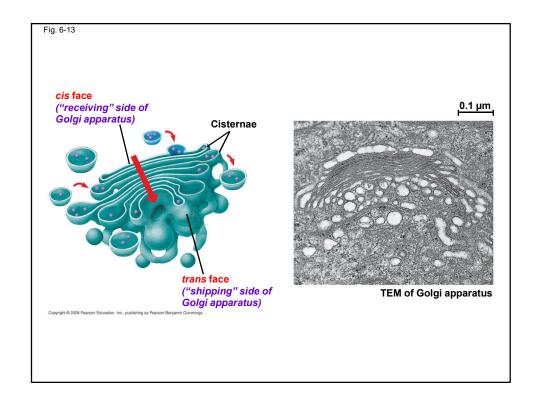

- Distributes transport vesicles ► proteins surrounded by membranes
- Is a membrane factory for the cell

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

# The Golgi Apparatus: Shipping and Receiving Center

- The Golgi apparatus consists of flattened membranous sacs called cisternae
- Functions of the Golgi apparatus:
  - -Modifies products of the ER
  - Manufactures certain macromolecules
  - Sorts and packages materials into transport vesicles

- Functions of the Golgi apparatus:
  - -Modifies products of the ER
  - Manufactures certain macromolecules
  - -Sorts and packages materials into transport vesicles

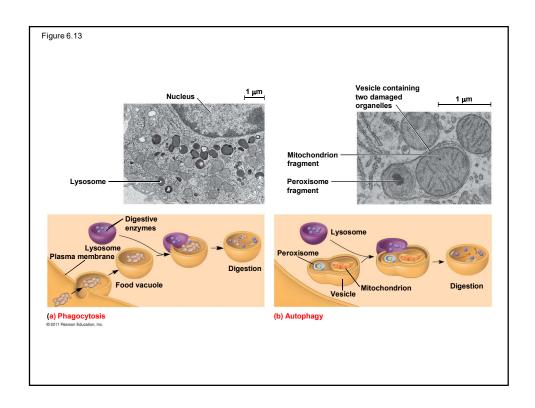

### **Lysosomes:** Digestive Compartments

- A lysosome is a membranous sac of hydrolytic enzymes that can digest macromolecules
- Lysosomal enzymes can <u>hydrolyze</u> proteins, fats, polysaccharides, and nucleic acids.
- Lysosomal enzymes work best in the acidic environment

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

- Some types of cell can engulf another cell by <u>phagocytosis</u>
  - this forms a food vacuole
- A lysosome <u>fuses with the food vacuole</u> and <u>digests</u> the molecules

 Lysosomes also use enzymes to <u>recycle</u> the cell's own organelles and macromolecules, a process called autophagy

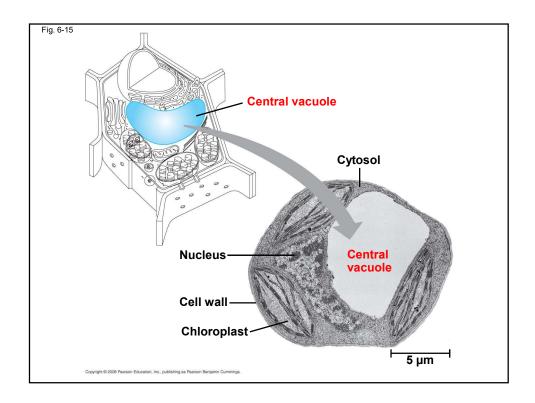

### **Vacuoles**

### **Diverse Maintenance Compartments**

A <u>plant cell or fungal</u> cell may have <u>one</u>
 or <u>several Vacuoles</u> <u>derived</u> from
 endoplasmic reticulum and Golgi
 apparatus

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

- Types of Vacuoles:
- Food vacuoles ► formed by phagocytosis
- Contractile vacuoles in many freshwater protists
   Dump excess water out of cells
- Central vacuoles 
   in plant cells 
   hold organic compounds and water

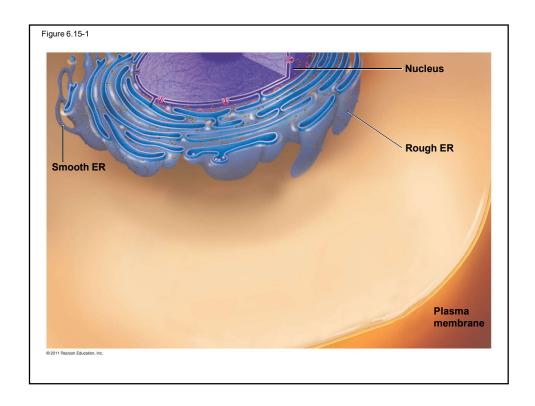

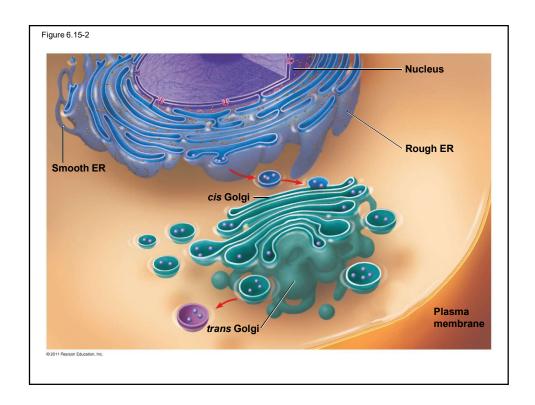

## The Endomembrane System:

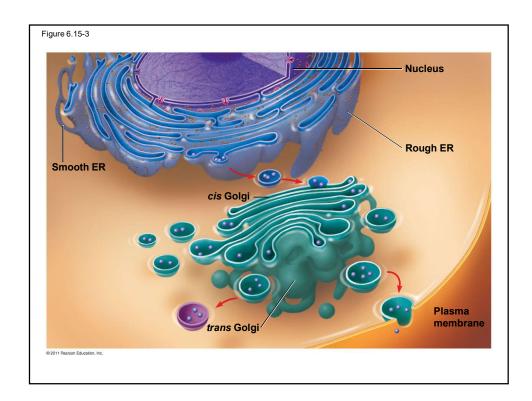

#### A Review

 The endomembrane system is a complex and dynamic player in the cell's

# compartmental organization

Mitochondria and chloroplasts change energy from one form to another

- Mitochondria are the sites of cellular respiration, a metabolic process that generates ATP
- Chloroplasts, found in plants and algae, are the sites of photosynthesis

# **The Evolutionary Origins of Mitochondria and Chloroplasts**

- Mitochondria and chloroplasts have similarities with bacteria:
  - Enveloped by a double membrane
  - Contain free ribosomes and circular DNA molecules
  - Grow and reproduce somewhat independently in cells

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cummings

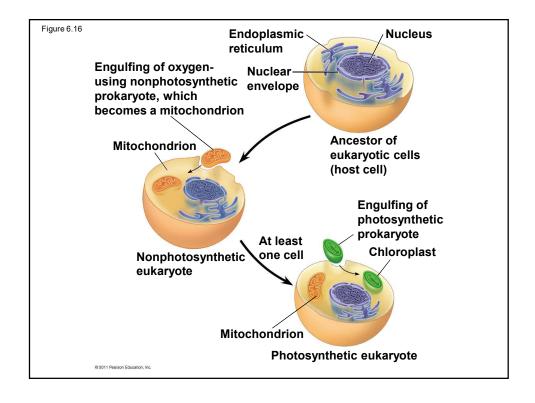

- The Endosymbiont theory
  - An early ancestor of eukaryotic cells engulfed a nonphotosynthetic prokaryotic cell, which formed an endosymbiont relationship with its host
  - The host cell and endosymbiont merged into a single organism, a eukaryotic cell with a

### mitochondrion

© 2011 Pearson Education Inc

#### At least one of these cells may

photosynthetic
prokaryote, becoming the ancestor of cells that contain chloroplasts

#### Mitochondria:

### **Chemical Energy Conversion**

- Mitochondria are in <u>nearly all eukaryotic</u> cells
- They have a smooth outer membrane and an <u>inner membrane folded</u> <u>into cristae</u>

MTO-GHOKDRIA

Inner membrane

Cristae

Inner membrane

Outer membrane

ONA

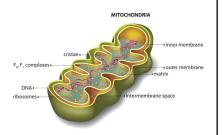

Intermembrane space

Copyright © 2008 Pearson Education, Inc., publishing as Pearson Benjamin Cumming

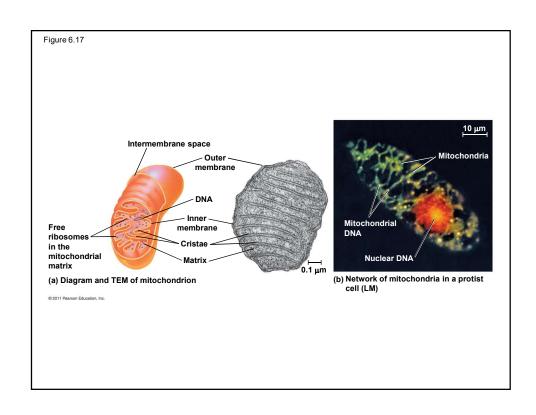

#### The inner membrane creates

## two compartments:

- -intermembrane space and
- -mitochondrial matrix

- Some metabolic steps of cellular respiration are catalyzed in the mitochondrial matrix
- Cristae present a <u>large</u> <u>surface area</u> for enzymes that <u>synthesize ATP</u>

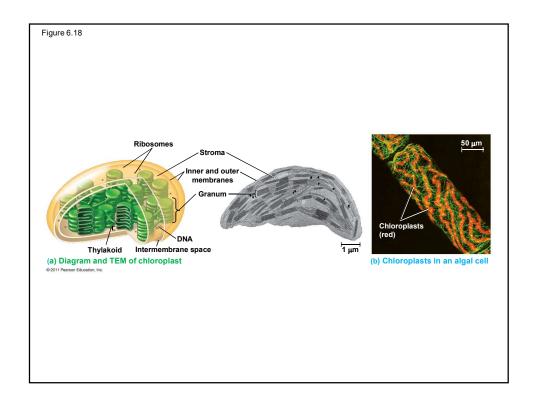

# **Chloroplasts: Capture of Light Energy**

- Chloroplasts contain the green pigment chlorophyll, as well as enzymes and other molecules that function in photosynthesis
- Chloroplasts are found in leaves and other green organs of plants and in algae

© 2011 Pearson Education, Inc

- Chloroplast structure includes
  - Thylakoids, membranous <u>Sacs</u>, stacked to form a granum
  - -Stroma, the internal fluid
- The <u>chloroplast</u> is one of a group of plant organelles, called <u>plastids</u>

© 2011 Pearson Education Inc

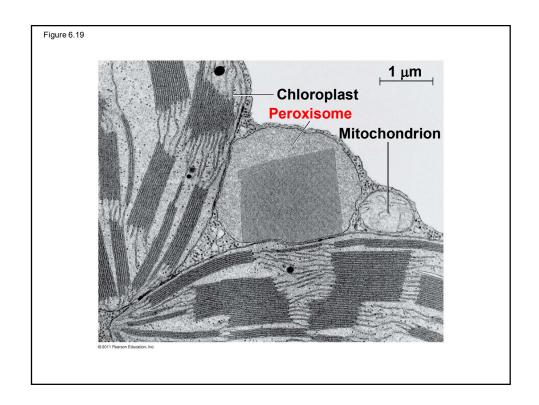

### **Peroxisomes: Oxidation**

- Peroxisomes are specialized metabolic compartments bounded by a single membrane
- Peroxisomes produce <u>hydrogen peroxide</u> and convert it to water

© 2011 Pearson Education Inc

## **Peroxisomes**

- Peroxisomes perform reactions with many different functions
- How peroxisomes are related to other organelles is still unknown

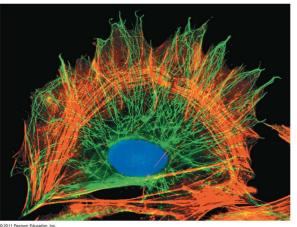

# The cytoskeleton is a network of fibers that organizes structures and activities in the cell

- The cytoskeleton is a network of fibers extending throughout the cytoplasm
- It <u>organizes</u> the cell's structures and activities, anchoring many organelles

© 2011 Pearson Education, Inc

## It is composed of three types of molecular structures.

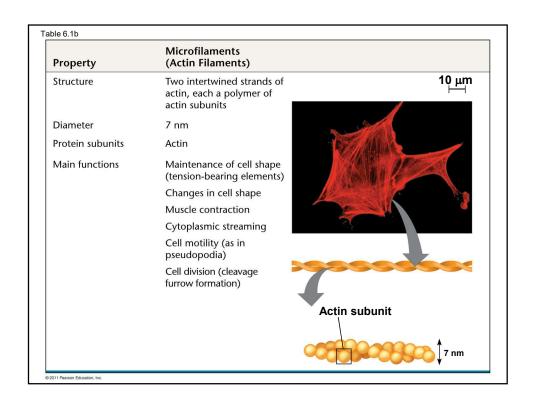

0 un

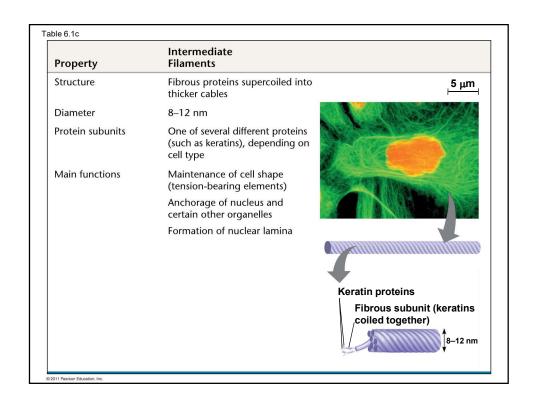

© 2011 Pearson Education, I

- Three main types of fibers make up the cytoskeleton
  - Microtubules are the thickest of the three components of the cytoskeleton
  - Microfilaments, also called <u>actin</u>
     <u>filaments</u>, are the <u>thinnest</u> components
  - Intermediate filaments are fibers with diameters in a middle range

© 2011 Pearson Education, Inc

Property	Microtubules (Tubulin Polymers)	
Structure	Hollow tubes; wall consists of 13 columns of tubulin molecules	<u>10 μm</u>
Diameter	25 nm with 15-nm lumen	
Protein subunits	Tubulin, a dimer consisting of $\alpha$ -tubulin and $\beta$ -tubulin	
Main functions	Maintenance of cell shape (compression-resisting "girders")	
	Cell motility (as in cilia or flagella)	
	Chromosome movements in cell division	
	Organelle movements	
		Column of tubulin dimers
		25 nm
		α \β \Tubulin dimer

## **Roles of the Cytoskeleton:**

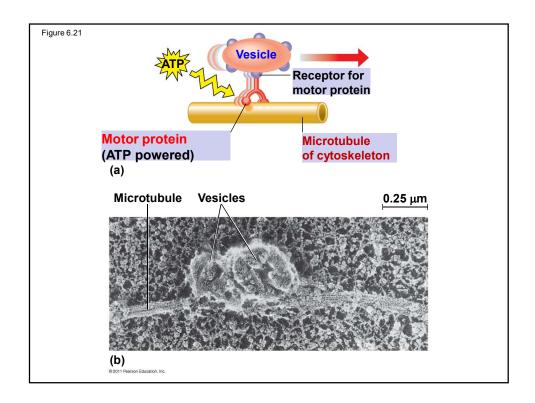

## **Support and Motility**

- The cytoskeleton helps to support the cell and maintain its shape
- It interacts with motor proteins to produce motility

© 2011 Pearson Education, Inc

## **Roles of the Cytoskeleton:**

- Inside the cell, vesicles can travel along "Monorals" provided by the cytoskeleton
- Recent evidence suggests that the cytoskeleton may help <u>regulate</u> biochemical activities

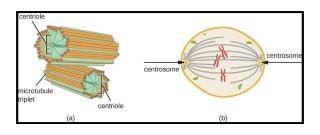

## **Centrosomes and Centrioles**

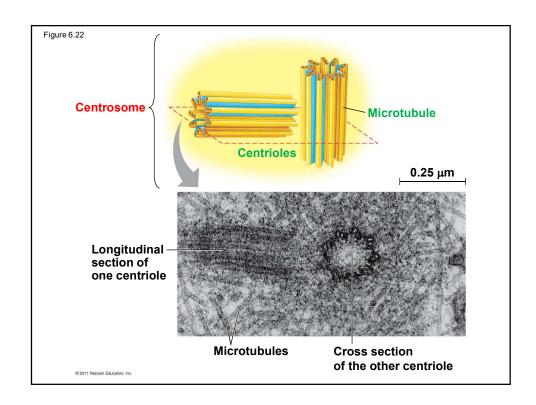

- In many cells, <u>microtubules</u>
   grow out from a <u>centrosome</u>
   near the nucleus
- The centrosome is a "microtubule-organizing center"

© 2011 Pearson Education In

## **Centrosomes and Centrioles**

 In animal cells, the centrosome has a pair of <u>centrioles</u>, each with <u>nine</u> triplets of <u>microtubules</u> arranged in a ring

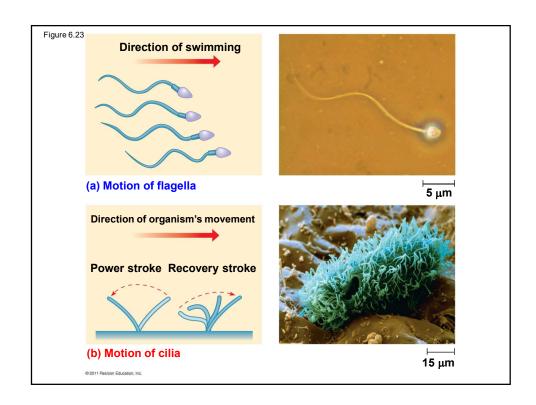

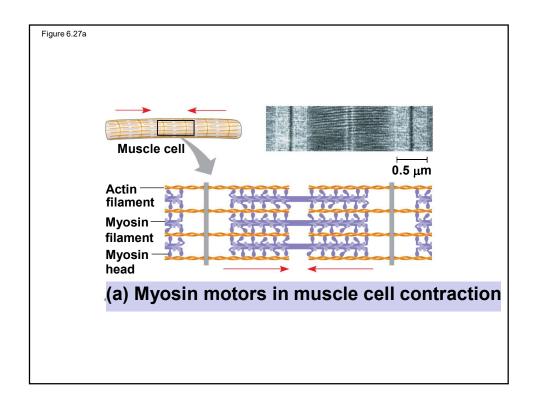

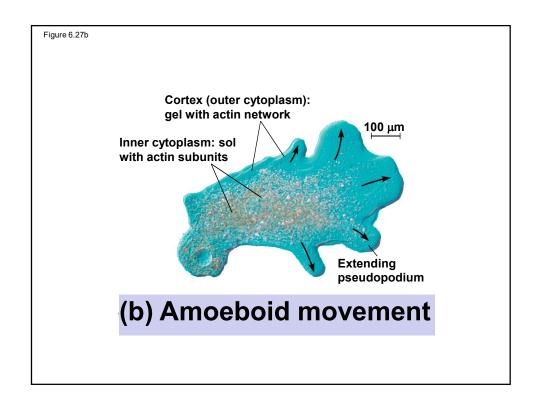

## Cilia and Flagella

- Microtubules control the beating of cilia and flagella, locomotor appendages of some cells
- Cilia and flagella differ in their beating patterns

© 2011 Pearson Education, Inc

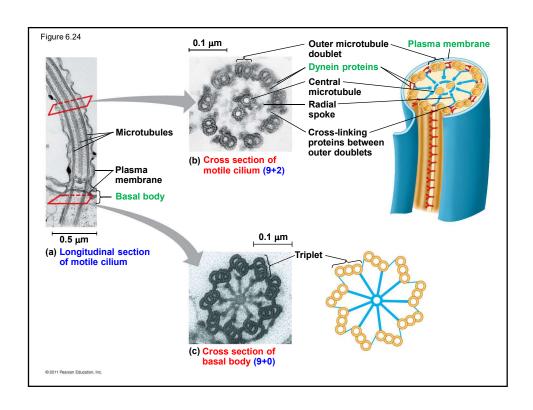

## Cilia and flagella share a common structure

- A core of microtubules sheathed by the plasma membrane
- A basal body that anchors the cilium or flagellum
- A motor protein called dynein,
   which drives the bending movements
   of a cilium or flagellum

# **Extracellular components** and connections between cells help coordinate cellular activities

- Most cells synthesize and secrete materials that are external to the plasma membrane
- These extracellular structures include
  - Cell walls of plants
  - The extracellular matrix (ECM) of animal cells
  - Intercellular junctions

## **Cell Walls of Plants**

- The cell wall is an extracellular structure that distinguishes plant cells from animal cells
- Prokaryotes, fungi, and some protists also have cell walls

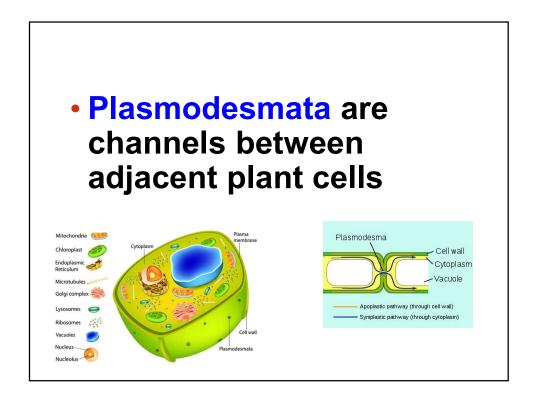

© 2011 Pearson Education Inc

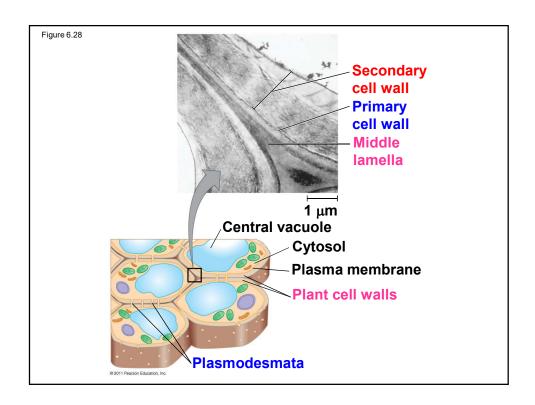

### **Cell Walls of Plants**

- The cell wall protects the plant cell, maintains its shape, and prevents excessive uptake of water
- Plant cell walls are made of cellulose fibers embedded in other polysaccharides and protein

- Plant cell walls may have multiple layers
  - Primary cell wall: relatively thin and flexible
  - Middle lamella: thin layer between primary walls of adjacent cells
  - Secondary cell wall (in some cells): added between the plasma membrane and the primary cell wall

© 2011 Pearson Education Inc

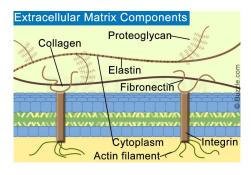

# The Extracellular Matrix (ECM) of Animal Cells

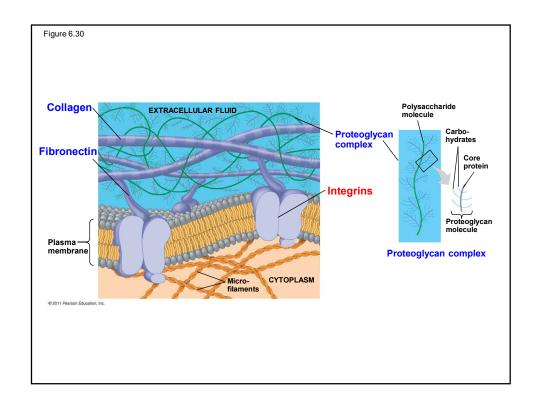

- Animal cells lack cell walls but are covered by an elaborate extracellular matrix (ECM).
- The ECM is made up of glycoproteins such as collagen, proteoglycans, and fibronectin

© 2011 Pearson Education, Inc

## The Extracellular Matrix (ECM) of Animal Cells

 ECM proteins bind to receptor proteins in the plasma membrane called integrins

- Functions of the ECM
  - Support
  - -Adhesion
  - Movement
  - -Regulation

© 2011 Pearson Education, Inc

### **Cell Junctions**

- Neighboring cells in tissues, organs, or organ systems often adhere, interact, and communicate through direct physical contact
- Intercellular junctions facilitate this contact

© 2011 Pearson Education, Inc

## **Cell Junctions**

- There are several types of intercellular junctions
  - Plasmodesmata
  - Tight junctions
  - Desmosomes
  - Gap junctions

#### Plasmodesmata: in Plant Cells

- Plasmodesmata are channels that perforate plant cell walls
- Through plasmodesmata, water and small solutes (and sometimes proteins and RNA) can pass from cell to cell

© 2011 Pearson Education, Inc

# Tight Junctions, Desmosomes, and Gap Junctions in Animal Cells

- At tight junctions, membranes of neighboring cells are pressed together, <u>preventing leakage</u> of extracellular fluid
- Desmosomes (anchoring junctions) <u>fasten</u>
   cells together into strong sheets

© 2011 Pearson Education Inc

# Gap junctions (communicating junctions) provide cytoplasmic channels between adjacent cells
