

# Objects & Classes

Liang, Introduction to Java Programming, Tenth Edition, (c) 2015 Pearson Education, Inc. All

# **OO Programming Concepts**

- Object-oriented programming (OOP) involves programming using objects.
- ❖ An *object* represents an entity in the real world that can be distinctly identified.
- ❖ For example, a student, a desk, a circle, a button, and even a loan can all be viewed as objects.
- An object has a unique identity, state, and behaviors.
  - The state of an object consists of a set of data fields (also known as properties) with their current values.
    - The *behavior* of an object is defined by a set of **methods**.

# **Objects and Classes**

- An object has both a state and behavior.
- The state defines the object, and the behavior defines what the object does.
- Classes are constructs that define objects of the same type.
- A Java class uses *variables* to define data fields and *methods* to define behaviors.
- Additionally, a class provides a special type of methods, known as constructors, which are invoked to construct objects from the class.

# Objects and Classes cont.

Class Name: Circle

A class template

Data Fields: radius is

Methods: getArea

Circle Object 1

Data Fields: radius is 10 Circle Object 2

Data Fields: radius is 25 Circle Object 3

Data Fields: radius is 125

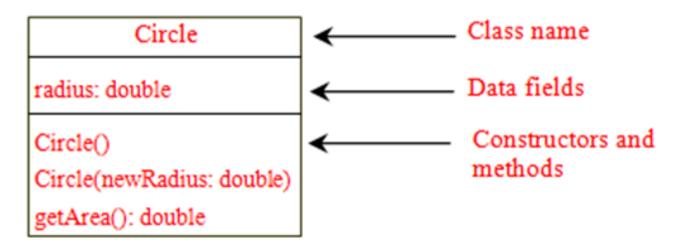

Three objects of the Circle class

#### **Circle Class**

```
class Circle {
 /** The radius of this circle */
 double radius = 1.0;
                                           Data field
 /** Construct a circle object */-
 Circle() {
                                           Constructors
  /** Construct a circle object */
 Circle(double newRadius) {
   radius = newRadius;
  /** Return the area of this circle */
 double getArea() {
                                          Method
    return radius * radius * 3.14159;
```

# **UML Class Diagram**

UML Class Diagram

circle1: Circle

radius = 1.0

circle2: Circle

radius = 25

circle3: Circle

radius = 125

UML notation for objects

#### Constructors

Constructors are a special kind of methods that are invoked to construct objects.

```
Circle() {
}

Circle(double newRadius) {
    radius = newRadius;
}
```

#### Constructors cont.

- ❖ A constructor with no parameters is referred to as a *no-arg constructor*.
- Constructors must have the same name as the class itself.
- Constructors do not have a return type—not even void.
- Constructors are invoked using the **new** operator when an object is created.
- Constructors play the role of initializing objects.

### **Creating Objects Using Constructors**

# new ClassName();

Example:

new Circle();

new Circle(5.0);

#### **Default Constructor**

- ❖ A class maybe defined without constructors.
- ❖ In this case, a no-arg constructor with an empty body is implicitly declared in the class.
- This constructor, called a default constructor, is provided automatically

# ONLY F no constructors are explicitly defined in the class.

#### **Declaring Object Reference Variables**

- To reference an object, assign the object to a reference variable.
- To declare a reference variable, use the syntax:

#### ClassName objectRefVar;

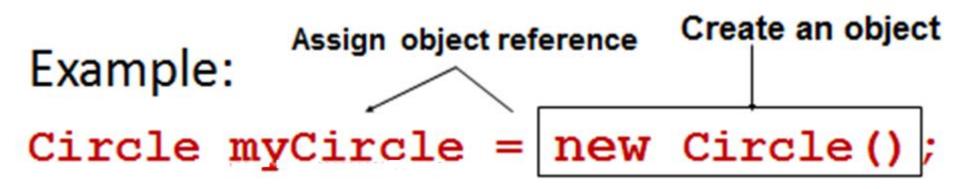

Example:

Circle myCircle;

#### Declaring/Creating Objects in a Single Step

ClassName objectRefVar = new ClassName();

# **Accessing Object's Members**

Referencing the object's data: objectRefVar.data

e.g., myCircle.radius

Invoking the object's method: objectRefVar.methodName(arguments)

e.g., myCircle.getArea()

### Reference Data Fields

- The data fields can be of reference types.
  - If a data field of a reference type does not reference any object, the data field holds a special literal value, null.
  - For example, the following **Student** class contains a data field **name** of the **String** type.

```
public class Student {
    String name; // name has default value null
    int age; // age has default value 0
    boolean isScienceMajor; // default false
    char gender; // default value '\u00000'
```

#### **Default Value for a Data Field**

The default value of a data field is:

null for a *reference* type

**0** for a *numeric* type

false for a boolean type

'\u0000' for a *char* type

However, Java assigns NO default value to a local variable inside a method.

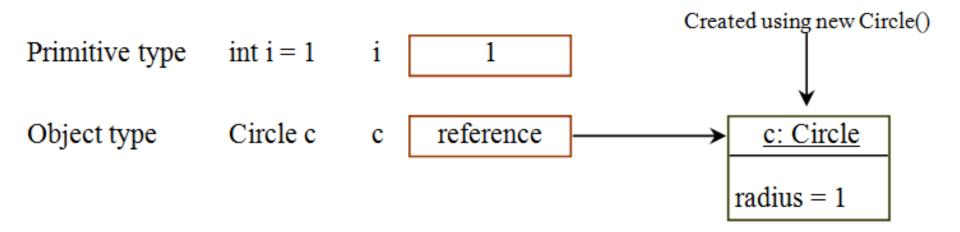

# Example

Java assigns no default value to a local variable inside a method.

```
public class Test {
 public static void main(String[] args) {
    int x; // x has no default value
    String y; // y has no default value
    System.out.println("x is " + x);
    System.out.println("y is " + y);
```

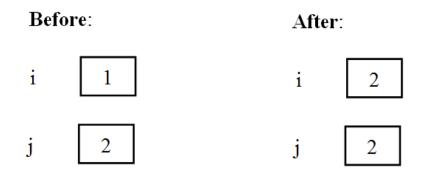

# Differences between Variables of Primitive Data Types and Object Types

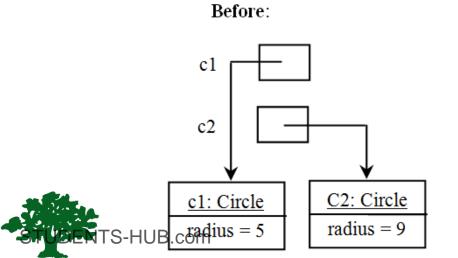

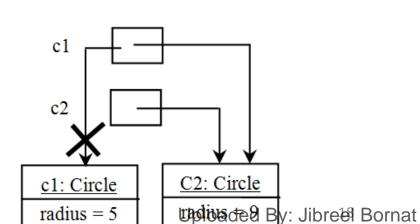

# Copying Variables of Primitive Data Types and Object Types

Primitive type assignment i = j

Object type assignment c1 = c2

After:

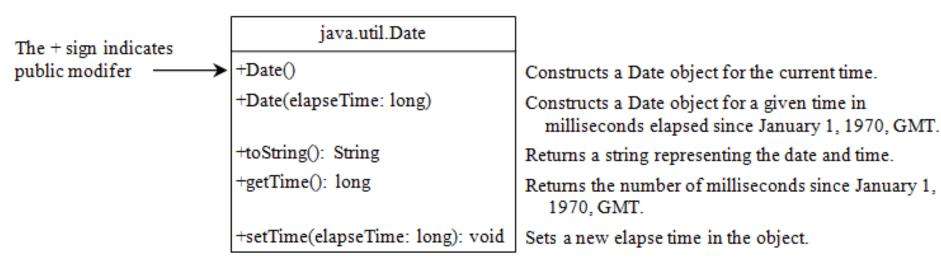

# **Garbage Collection**

- As shown in the previous figure, after the assignment statement c1 = c2, c1 points to the same object referenced by c2.
- The object previously referenced by **c1** is no longer referenced.
- This object is known as garbage.
- Garbage is automatically collected by JVM.

## The Date Class

- ❖ Java provides a system-independent encapsulation of date and time in the java.util.Date class.
- ❖ You can use the **Date** class to create an instance for the current date and time and use its **toString** method to return the date and time as a **string**.

# The Date Class Example

- For example, the following code: java.util.Date date = new java.util.Date(); System.out.println(date.toString());
  - displays a string like:

Mon Nov 04 19:50:54 IST 2013

### The Random Class

- ❖ You have used Math.random() to obtain a random double value between 0.0 and 1.0 (excluding 1.0).
- A more useful random number generator is provided in the **java.util.Random** class.

#### java.util.Random

+Random()

+Random(seed: long)

+nextInt(): int

+nextInt(n: int): int

+nextLong(): long

+nextDouble(): double

+nextFloat(): float

+nextBoolean(): boolean

Constructs a Random object with the current time as its seed.

Constructs a Random object with a specified seed.

Returns a random int value.

Returns a random int value between 0 and n (exclusive).

Returns a random long value.

Returns a random double value between 0.0 and 1.0 (exclusive).

Returns a random float value between 0.0F and 1.0F (exclusive).

Returns a random boolean value.

# Instance Variables, and Methods

Instance variables belong to a specific instance.

Instance methods are invoked by an instance of the class.

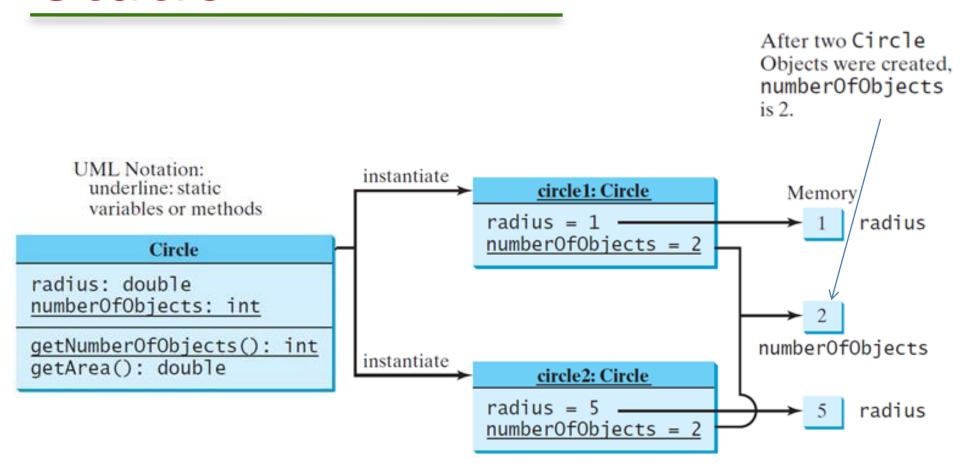

### **Static** Variables, Constants, and Methods

- Static variables are shared by all the instances of the class.
- Static methods are not tied to a specific object.
- Static constants are final variables shared by all the instances of the class.
- ❖ To declare static *variables*, *constants*, and *methods*, use the **Static** modifier.

# Static

#### **Static Variable**

- ❖ It is a variable which belongs to the class and not to the object (instance).
- Static variables are initialized only once, at the start of the execution. These variables will be initialized first, before the initialization of any instance variables.
- A single copy to be shared by all instances of the class.
- A static variable can be **accessed directly** by the **class name** and doesn't need any object.

### **Static Method**

- It is a method which belongs to the class and not to the object (instance).
- A static method can access only static data. It can not access non-static data (instance variables).
- A static method can call only other static methods and can not call a non-static method from it.
- A static method can be accessed directly by the class name and doesn't need any object.

Syntax : <*class-name>.*<*static-method-name>* 

A static method cannot refer to "this" or "super" keywords in anyway.

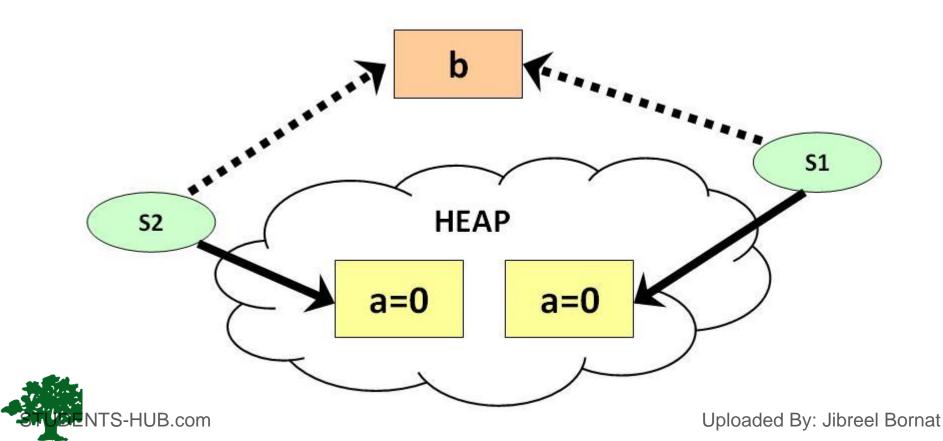

main method is static, since it must be accessible for an G-HUB. application to run, before any instantiation takes place! By: Jibreel Bornat

# Static example

```
class Student {
     int a; //initialized to zero
     static int b; //initialized to zero only when class is loaded
 4
       Student(){
        //Constructor incrementing static variable b
 6
        b++;
 8
        public void showData(){
10
           System.out.println("Value of a = "+a);
11
           System.out.println("Value of b = "+b);
12
13
     //public static void increment(){
14
15
    //a++;
     //}
16
17
18
19
20
     class Demo{
        public static void main(String args[]){
21
          Student s1 = new Student();
22
                                               C:\WINDOWS\system32\cmd.exe
          s1.showData();
23
          Student s2 = new Student();
24
                                              C:\workspace>java Demo
25
          s2.showData();
                                              Value\ of\ a =
         //Student.b++;
26
                                              Value\ of\ b=
         //s1.showData();
                                              Jalue of
```

# Static example cont.

Following diagram shows, how reference variables & objects are created and static variables are accessed by the different instances.

# Visibility Modifiers

- **By default**, the *class*, *variable*, or *method* can be accessed by any class in the same package.
- public: The class, data, or method is visible to any class in any package.
- Private: The data or methods can be accessed only by the declaring class.
- The get and set methods are used to read and modify private properties.

```
package p1;

public class C1 {
   public int x;
   int y;
   private int z;

public void m1() {
   }
   void m2() {
   }
   private void m3() {
   }
}
```

```
package p1;

public class C2 {
  void aMethod() {
    C1 o = new C1();
    can access o.x;
    can access o.y;
    cannot access o.z;

    can invoke o.m1();
    can invoke o.m2();
    cannot invoke o.m3();
  }
}
```

```
package p2;

public class C3 {
   void aMethod() {
     C1 o = new C1();
     can access o.x;
     cannot access o.y;
     cannot access o.z;

     can invoke o.m1();
     cannot invoke o.m2();
     cannot invoke o.m3();
   }
}
```

```
package p1;
class C1 {
    ...
}
```

```
package p1;
public class C2 {
  can access C1
}
```

```
package p2;

public class C3 {
   cannot access C1;
   can access C2;
}
```

The **private** modifier restricts access to **within a class**.

The default modifier restricts access to within a package.

The public modifier enables unrestricted access. Jibreel Bornat

#### **NOTE**

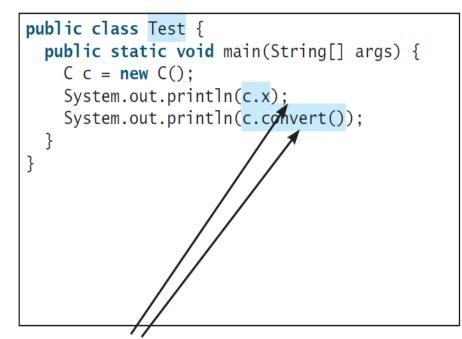

An object **cannot** access its private members, as shown in (**b**). It is OK, however, if the object is declared in its own class, as shown in (**a**).

```
public class C {
  private boolean x;

public static void main(String[] args) {
  C c = new C();
  System.out.println(c.x);
  System.out.println(c.convert());
}

private int convert() {
  return x ? 1 : -1;
  }
}
```

```
(a) This is okay because object c is used inside the class C.
```

(b) This is wrong because **x** and **convert** are private in class **C**.

### Example of Data Field Encapsulation

The - sign indicates private modifier —

Circle

-radius: double

-numberOfObjects: int

+Circle()

+Circle(radius: double)

+getRadius(): double

+setRadius(radius: double): void

+getNumberOfObject(): int

+getArea(): double

The radius of this circle (default: 1.0).

The number of circle objects created.

Constructs a default circle object.

Constructs a circle object with the specified radius.

Returns the radius of this circle.

Sets a new radius for this circle.

Returns the number of circle objects created.

Returns the area of this circle.

#### **Overloading Methods and Constructors**

- In a class, there can be several methods with the same name. However they must have different signature.
- The signature of a method is comprised of its name, its parameter types and the order of its parameter.
- The signature of a method is not comprised of its return type nor its visibility nor its thrown exceptions.

# Passing Objects to Methods

- A Passing by value for primitive type value (the **value** is passed to the parameter).
- A Passing by value for reference type value (the value is the **reference** to the object).

#### **Passing Objects to Methods**

```
public class TestPassObject {
 public static void main(String[] args) {
     Circle myCircle = new Circle(1);
    // Print areas for radius 1, 2, 3, 4, and 5.
    int n = 5;
    printAreas(myCircle, n);
    System.out.println("\n" + "Radius is " + myCircle.getRadius());
    System.out.println("n is " + n);
 /** Print a table of areas for radius */
 public static void printAreas( Circle c, int times) {
   System.out.println("Radius \t\tArea");
   while (times >= 1) {
       System.out.println(c.getRadius() + "\t\t" + c.getArea());
       c.setRadius(c.getRadius() + 1);
       times--;
```

## **Array of Objects**

#### Circle[] circleArray = new Circle[10];

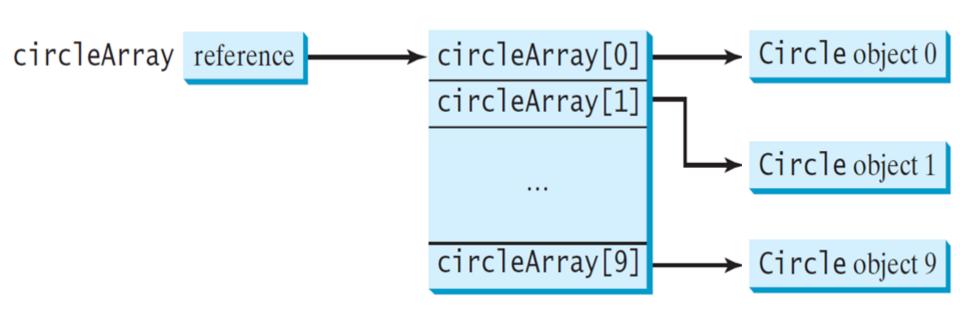

- An array of objects is actually an array of reference variables.
- So invoking circleArray[1].getArea() involves two levels of referencing as shown in the next figure.

circleArray references to the entire array.
circleArray[1] references to a Circle object.

## **Array of Objects**

#### Circle[] circleArray = new Circle[10];

circleArray[0] = new Circle();
circleArray[1] = new Circle();
:
circleArray[9] = new Circle();
Uploaded By: Jibreel Bornat

#### **Immutable** Objects and Classes

If the contents of an object (instance) can't be changed once the object is created, the object is called an immutable object and its class is called an

immutable class.

#### **Immutable** Objects and Classes

If you delete the set method in the Circle class, the class would be immutable because radius is private and cannot be changed without a set method.

```
public class Circle {
 private double radius = 1;
 public double getArea() {
  return radius * radius * Math.PI;
 public void setRadius(double r) {
   radius = r;
```

## **Immutable** Objects and Classes

- A class with all private data fields and without mutators is not necessarily immutable.
- ❖ For example, the following class **Student** has all **private** data fields and no **mutators**, but it is mutable!!!

#### Example

```
import java.util.Date;
public class Student {
 private int id;
 private Date birthDate;
 public Student(int ssn, Date newBD) {
    id = ssn;
    birthDate = newBD;
  public int getId() {     return id;     }
  public Date getBirthDate() {     return birthDate;
```

Uploaded By: Jibreel Bornat

```
public class Test {
  public static void main(String[] args) {
    java.util.Date bd = new java.util.Date();
    Student student = new Student(111223333, bd);
    java.util.Date date = student.getBirthDate();
    date.setMonth(5); // Now the student birthdate is changed!
  }
}
```

#### What Class is Immutable?

- For a class to be immutable:
  - It must mark all data fields private.
  - Provide no mutator methods.
  - No accessor methods that would return a reference to a mutable data field object.

# Scope of Variables

- The scope of instance and static variables is the entire class. They can be declared anywhere inside a class.
- The scope of a **local** variable starts from its declaration and continues to the end of the block that contains the variable.
- A local variable **must** be initialized explicitly before it can be used.

## Scope of Variables

What is the output?

```
public class A{
 int year = 2014; // instance variable
 void p() {
   System.out.println("Year: "+ year);
   int year = 2015; // local variable
   System.out.println("Year: "+ year);
```

# The this Keyword

- The this keyword is the name of a reference that refers to an object itself.
- One common use of the this keyword is reference a class's hidden data fields.
- Another common use of the this keyword to enable a constructor to invoke another constructor of the same class.

#### Reference the Hidden Data Fields

```
public class F {
  private int i = 5;
  private static double k = 0;

  void setI(int i) {
    this.i = i;
  }

  static void setK(double k) {
    F.k = k;
  }
}
```

```
Suppose that f1 and f2 are two objects of F.
F f1 = new F(); F f2 = new F();
Invoking f1.setI(10) is to execute
   this.i = 10, where this refers f1
```

#### Calling Overloaded Constructor

```
public class Circle {
  private double radius;
  public Circle(double radius) {
    this.radius = radius;
                               this must be explicitly used to reference the data
                               field radius of the object being constructed
  public Circle() {
    this (1.0);
                              this is used to invoke another constructor.
  public double getArea() {
     return this.radius * this.radius * Math.PI;
```

Every instance variable belongs to an instance represented by this, which is normally omitted

Uploaded By: Jibre Bornat
