

ENCS3340 - Artificial Intelligence

Uninformed Search

Uninformed Search Strategies

- **Uninformed** search strategies use only the information available in the problem definition
- Examples:
 - Breadth-first search
 - Depth-first search
 - Iterative deepening search
 - Uniform-cost search

Breadth-First Search

- all the nodes reachable from the current node are explored first
 - Expand shallowest unexpanded node
 - achieved by the TREE-SEARCH method by appending newly generated nodes at the end of the search queue

```
function GENERAL-SEARCH(problem) returns solution  
  
    return TREE-SEARCH(problem, FIFO-QUEUE())
```

- Implementation: fringe is a FIFO queue, i.e., new successors go at end

Goal

Note:

The goal test is positive for this node, and a solution is found in 24 steps.

Fringe: [25,26,27,28,29,30,31]

Properties of Breadth-First Search

Time Complexity	$O(b^{d+1})$
Space Complexity	$O(b^{d+1})$
Completeness	yes (for finite b)
Optimality	yes (for non-negative path costs)

b	branching factor
d	depth of the optimal solution

Breadth-First Search for Graphs

- Keep a set of explored (visited) nodes.
- When a node is expanded, add the generated nodes to frontier **only if not in the frontier or explored set**

Example: BFS for Graphs

- For the following state space, list all the visited nodes and draw the search tree to go from S to G using BFS. What is the returned solution?

Example: BFS for Graphs (Cont.)

- Visited Nodes: S, A, B, C, H, G
- Solution (Path to goal): S, B, G

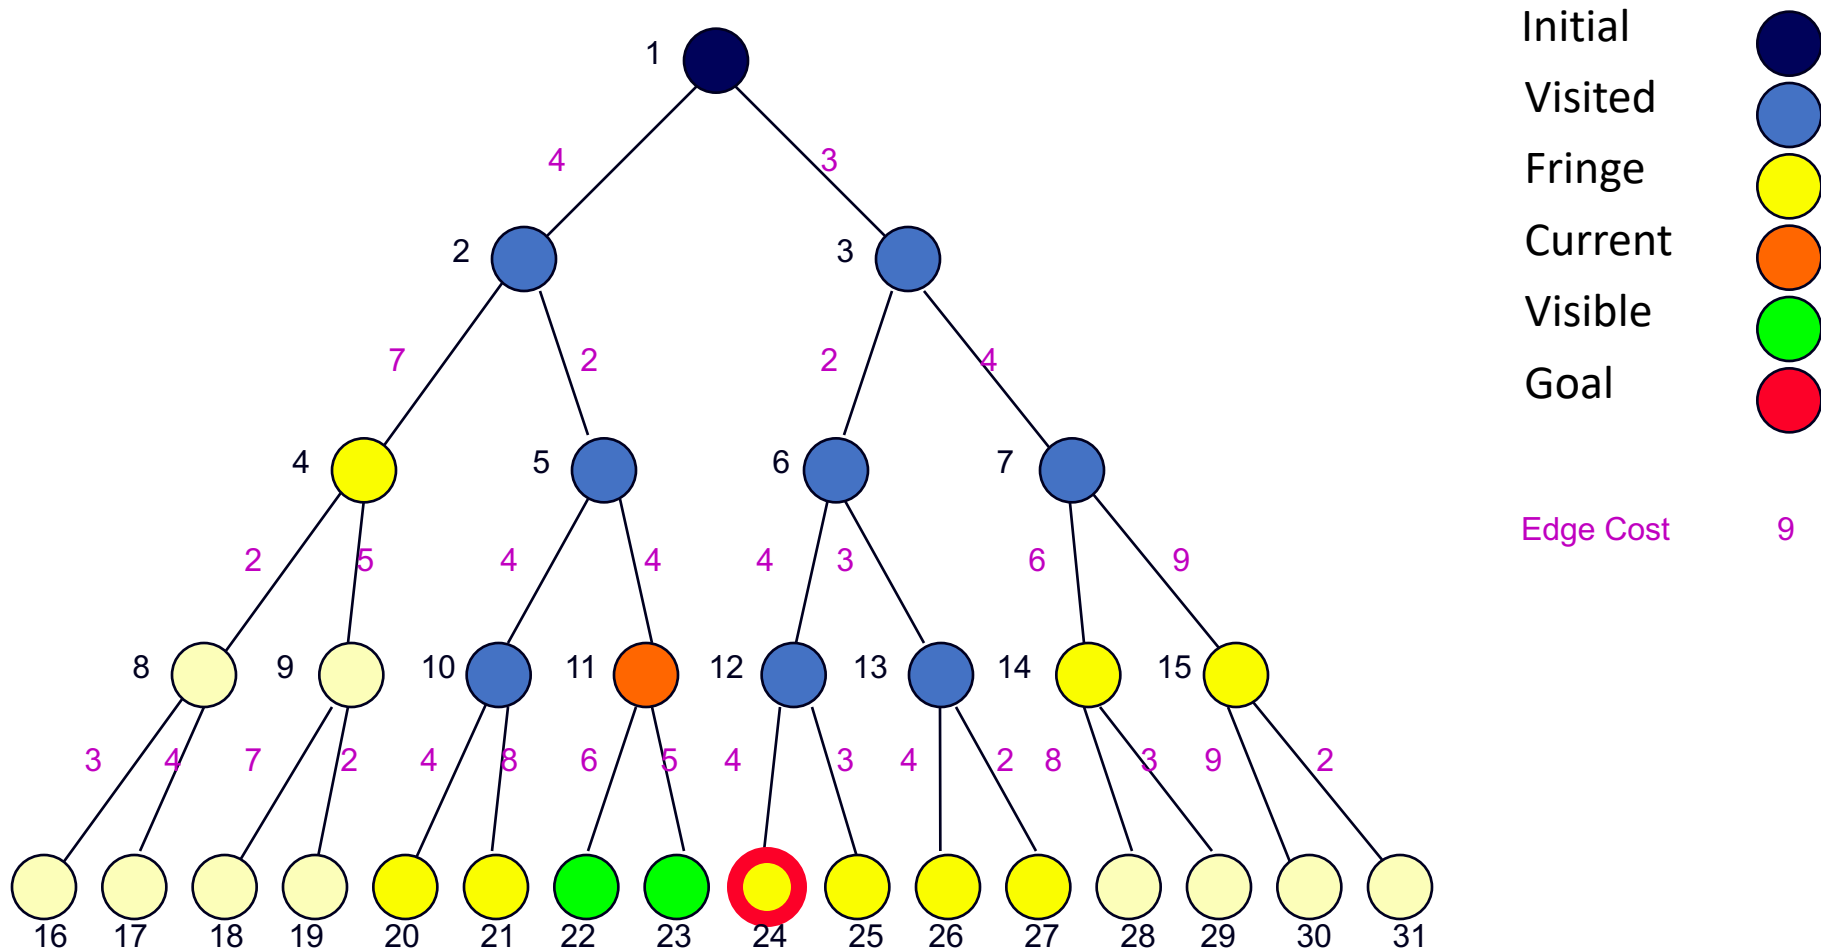

Uniform-Cost Search

- the nodes with the lowest cost are explored first
 - similar to BREADTH-FIRST, but with an evaluation of the cost for each reachable node
 - $g(n) = \text{path cost}(n) = \text{sum of individual edge costs to reach the current node}$
- Implementation: fringe is a queue ordered by path cost (priority queue)
- Equivalent to breadth-first if step costs all equal

```
function UNIFORM-COST-SEARCH(problem) returns solution  
  
    return TREE-SEARCH(problem, COST-FN, FIFO-QUEUE())
```

Uniform-Cost Snapshot

Goal reached!

Notation: [**Bold+Yellow: Current Node**; White: Old Fringe Node; **Green+Italics: New Fringe Node**].

Assumption: New nodes with the same cost as existing nodes are added after the existing node.

Properties of Uniform-Cost Search

Time Complexity	$O(b^{C^*/e})$
Space Complexity	$O(b^{C^*/e})$
Completeness	yes (finite b , step costs $\geq e$)
Optimality	yes

b	branching factor
C^*	cost of the optimal solution
e	minimum cost per action

Uniform-Cost Search for Graphs

- Keep a set of explored (visited) nodes.
- When a node is expanded, add the generated nodes to frontier **only if not in the frontier or explored set**
 - **If the state of the generated node is in the frontier but with higher cost, replace that frontier node with newly generated node**

Breadth-First vs. Uniform-Cost

- breadth-first always expands the shallowest node
 - only optimal if all step costs are equal
- uniform-cost considers the overall path cost
 - optimal for any (reasonable) cost function
 - non-zero, positive
 - gets bogged down in trees with many fruitless, short branches
 - low path cost, but no goal node
- both are complete for non-extreme problems
 - finite number of branches
 - strictly positive search function

Depth-First Search

- continues exploring newly generated nodes
 - achieved by the TREE-SEARCH method by appending newly generated nodes at the beginning of the search queue
- Implementation: fringe = LIFO queue, i.e., put successors at front

```
function DEPTH-FIRST-SEARCH(problem) returns solution  
  
    return TREE-SEARCH(problem, LIFO-QUEUE())
```

Time Complexity	$O(b^m)$
Space Complexity	$O(b \cdot m)$
Completeness	no (for infinite branch length)
Optimality	no

b	branching factor
m	maximum path length

Depth-First Search

- Given the following state space (tree search), give the sequence of visited nodes when using DFS (assume that the node O is the goal state):

Depth-First Search

- A,

Depth-First Search

- A, B,

Depth-First Search

- A, B, F,

Depth-First Search

- A, B, F,
- G,

Depth-First Search

- A, B, F,
- G, K,

Depth-First Search

- A, B, F,
- G, K,
- L,

Depth-First Search

- A, B, F,
- G, K,
- L, O: Goal State

Depth-First Search

- The returned solution is the sequence of operators in the path:
A, B, G, L, O

Example: DFS for Graphs

- For the following state space, list all the visited nodes and draw the search tree to go from S to G using DFS. What is the returned solution?

Example: DFS for Graphs (Cont.)

- Visited Nodes: S, A, C, G
- Solution (Path to goal): S, A, C, G

Depth-First vs. Breadth-First

- depth-first goes off into one branch until it reaches a leaf node
 - not good if the goal is on another branch
 - neither complete nor optimal
 - uses much less space than breadth-first
- breadth-first is more careful by checking all alternatives
 - complete and optimal
 - very memory-intensive

Depth-Limited Search

- similar to depth-first, but with a limit
 - overcomes problems with infinite paths
 - sometimes a depth limit can be inferred or estimated from the problem description
 - based on the TREE-SEARCH method
 - must keep track of the depth

```
function DEPTH-LIMITED-SEARCH(problem, depth-limit) returns solution  
  
    return TREE-SEARCH(problem, depth-limit, LIFO-QUEUE())
```

Time Complexity	$O(b^l)$
Space Complexity	$O(b * l)$
Completeness	no (goal beyond l , or infinite branch length)
Optimality	no

b	branching factor
l	depth limit

Iterative Deepening

- applies LIMITED-DEPTH with increasing depth limits
- combines advantages of BREADTH-FIRST and DEPTH-FIRST methods
- many states are expanded multiple times
 - doesn't really matter because the number of those nodes is small
- in practice, one of the best uninformed search methods
 - for large search spaces, unknown depth

```
function ITERATIVE-DEEPENING-SEARCH(problem) returns solution  
  for depth := 0 to unlimited do  
    result := DEPTH-LIMITED-SEARCH(problem, depth-limit)  
    if result != cutoff then return result
```

Time Complexity	$O(b^d)$
Space Complexity	$O(b*d)$
Completeness	yes (finite b)
Optimality	yes (all step costs identical)

b branching factor
 d depth of optimal solution

Iterative deepening search

Limit = 0

Iterative deepening search

Limit = 1

Iterative deepening search

Limit = 2

Iterative deepening search

Limit = 3

Example IDS

Depth bound = 1

Depth bound = 2

Depth bound = 3

Depth bound = 4

Stages in Iterative-Deepening Search

Bi-directional Search

- search simultaneously from two directions
 - forward from the initial and backward from the goal state
- may lead to substantial savings if it is applicable
- has severe limitations
 - predecessors must be generated, which is not always possible
 - search must be coordinated between the two searches
 - one search must keep all nodes in memory

Time Complexity	$O(b^{d/2})$
Space Complexity	$O(b^{d/2})$
Completeness	yes (b finite, breadth-first for both directions)
Optimality	yes (all step costs identical, breadth-first for both directions)

b	branching factor
d	depth of optimal solution

Improving Search Methods

- assumption for improvements
 - remember information about the search so far
 - all nodes visited so far
 - path to the current node
- make algorithms more efficient
 - avoiding repeated states
 - utilizing memory efficiently
- use additional knowledge about the problem => informed search
 - properties (“shape”) of the search space
 - more interesting areas are investigated first
 - pruning of irrelevant areas
 - areas that are guaranteed not to contain a solution can be discarded

Comparing Uninformed Search Strategies

Criterion	Breadth-First	Uniform-Cost	Depth-First	Depth-Limited	Iterative Deepening	Bidirectional (if applicable)
Complete?	Yes ^a	Yes ^{a,b}	No	No	Yes ^a	Yes ^{a,d}
Time	$O(b^d)$	$O(b^{1+\lceil C^*/\epsilon \rceil})$	$O(b^m)$	$O(b^l)$	$O(b^d)$	$O(b^{d/2})$
Space	$O(b^d)$	$O(b^{1+\lceil C^*/\epsilon \rceil})$	$O(bm)$	$O(bl)$	$O(bd)$	$O(b^{d/2})$
Optimal?	Yes ^c	Yes	No	No	Yes ^c	Yes ^{c,d}

Evaluation of tree-search strategies. b is the branching factor; d is the depth of the shallowest solution; m is the maximum depth of the search tree; l is the depth limit. Superscript caveats are as follows: ^a complete if b is finite; ^b complete if step costs $\geq \epsilon$ for positive ϵ ; ^c optimal if step costs are all identical; ^d if both directions use breadth-first search.
