

Elementary Programming

Liang, Introduction to Java Programming, Tenth Edition, (c) 2015 Pearson Education, Inc. All

Trace a Program Execution

```
public class ComputeArea {
 /** Main method */
 public static void main(String[] args) {
                                                                   memory
  double radius;
  double area;
                                                          radius
                                                                         20
  // Assign a radius
                                                                      1256.636
                                                          area
  radius = 20;
  // Compute area
  area = radius * radius * 3.14159;
  // Display results
  System.out.println("The area for the circle of radius " +
   radius + " is " + area);
                                Command Prompt
                                                                          _ | D | X
                                c:∖book>java ComputeArea
                                The area for the circle of radius 20.0 is 1256.636
```

Identifiers

- An identifier is a sequence of characters that consist of letters, digits, underscores (_), and dollar signs (\$).
- An identifier must start with a letter, an underscore (_), or a dollar sign (\$). It cannot start with a digit.
 - An identifier cannot be a reserved word. (See Appendix A, "Java Keywords").
- An identifier cannot be true, false, or null.
- An identifier can be of any length.

Declaring Variables

```
int x;  // Declare x to be an integer variable
double radius;  // Declare radius to be a double variable
char a;  // Declare a to be a character variable
```

Assignment Statements

Declaring and Initializing in One Step

```
int x = 1;
double d = 1.4;
```

Named Constants

```
final datatype CONSTANTNAME = VALUE;
final double PI = 3.14159;
final int SIZE = 3;
```

Naming Conventions

- Choose meaningful and descriptive names.
- Variables and method names:
 - Use lowercase.
 - If the name consists of several words, concatenate all in one, use lowercase for the first word, and capitalize the first letter of each subsequent word in the name.
 - For example, the variables radius and area, and the method computeArea.

Naming Conventions, cont.

Class names:

- Capitalize the first letter of each word in the name.
- For example, the class name ComputeArea.

Constants:

- Capitalize all letters in constants, and use underscores to connect words.
- For example, the constant PI and MAX_VALUE

Numerical Data Types

Name	Range	Storage Size
byte	-2^{7} to 2^{7} – 1 (-128 to 127)	8-bit signed
short	-2^{15} to $2^{15} - 1$ (-32768 to 32767)	16-bit signed
int	-2^{31} to $2^{31} - 1$ (-2147483648 to 2147483647)	32-bit signed
long	-2^{63} to $2^{63} - 1$ (i.e., -9223372036854775808 to 9223372036854775807)	64-bit signed
float	Negative range: -3.4028235E+38 to -1.4E-45 Positive range: 1.4E-45 to 3.4028235E+38	32-bit IEEE 754
double	Negative range: -1.7976931348623157E+308 to -4.9E-324	64-bit IEEE 754
	Positive range: 4.9E-324 to 1.7976931348623157E+308	

double vs. float

The double type values are more accurate than the float type values. For example,

```
System.out.println("1.0 / 3.0 is " + 1.0 / 3.0);
         16 digits
System.out.println("1.0F / 3.0F is " + 1.0F / 3.0F);
         displays 1.0F / 3.0F is 0.33333334
                              7 digits
```

Increment and Decrement Operators

Operator	Name	Description	Example (assume $i = 1$)
++var	preincrement	Increment var by 1, and use the new var value in the statement	<pre>int j = ++i; // j is 2, i is 2</pre>
var++	postincrement	Increment var by 1, but use the original var value in the statement	<pre>int j = i++; // j is 1, i is 2</pre>
var	predecrement	Decrement var by 1, and use the new var value in the statement	<pre>int j =i; // j is 0, i is 0</pre>
var	postdecrement	Decrement var by 1, and use the original var value in the statement	<pre>int j = i; // j is 1, i is 0</pre>

Numeric Type Conversion

Consider the following statements:

```
byte i = 100;
```

long
$$k = i * 3 + 4;$$

double
$$d = i * 3.1 + k / 2;$$

Conversion Rules

- When performing a binary operation involving two operands of different types, Java automatically converts the operand based on the following rules:
- 1. If one of the operands is **double**, the other is converted into double.
- 2. Otherwise, if one of the operands is **float**, the other is converted into float.
- 3. Otherwise, if one of the operands is **long**, the other is converted into long.
 - Otherwise, both operands are converted into int.

Type Casting

Implicit casting

```
double d = 3;
```

(type widening)

Explicit casting

```
int i = (int)3.0;
```

int i = (int)3.9;

(type narrowing)

(Fraction part is truncated)

What is wrong?

int x = 6 / 2.0;

range increases

byte, short, int, long, float, double

Character Data Type

```
char letter = 'A'; (ASCII)

char numChar = '4'; (ASCII)

char letter = '\u0041'; (Unicode)

char numChar = '\u0034'; (Unicode)
```

NOTE: The increment and decrement operators can also be used on **char** variables to get the next or preceding Unicode character. For example, the following statements display character **b**.

char ch = 'a';
System.out.println(++ch);

The String Type

❖ The char type only represents one character. To represent a string of characters, use the data type called String. For example:

String message = "Welcome to Java!";

- String is actually a predefined class in the Java library.
- The String type is not a primitive type. It is known as a *reference* type.

String Concatenation

```
// Three strings are concatenated
String message = "Welcome " + "to " + "Java";
// String Chapter is concatenated with number 2
String s = "Chapter" + 2; // s becomes Chapter2
// String Supplement is concatenated with character B
String s1 = "Supplement" + 'B'; // s1 becomes SupplementB
```

Console Input

- You can use the Scanner class for console input.
- Java uses System.in to refer to the standard input device (i.e. Keyboard).

```
import java.util.Scanner;
public class Test{
  public static void main(String[] s){
    Scanner input = new Scanner(System.in);
    System.out.println("Enter X:");
     int x = input.nextInt();
    System.out.println("You entered: "+ x);
```

Reading Numbers from the Keyboard

Scanner input = new Scanner(System.in); int value = input.nextInt();

Method	Description
nextByte()	reads an integer of the byte type.
nextShort()	reads an integer of the short type.
nextInt()	reads an integer of the int type.
nextLong()	reads an integer of the long type.
nextFloat()	reads a number of the float type.
nextDouble()	reads a number of the double type.
