

chapter 1

A database is a collection of data, typically describing the activities of one or more related organizations

Entities & Relationships

DBMS: is a software designed to assist in maintaining and utilizing large collection of data

1.4 Advantages of DBMS

- Data independence
- Efficient data access
- Data Integrity and security
- Data Administration
- Concurrent access and crash recovery
- Reduced Application development time

1.5

data model: a collection of high-level data description constructs that hide many low-level storage details.

- semantic data model
- schema: a description of data in terms of data model

1.5.2 levels of abstraction

- conceptual (logical) schema: describes the stored data
 - describes all relations stored in db

arriving at a good conceptual schema (conceptual db design)

- physical schema → additional storage details

↳ how relations described in the conceptual schema are actually stored on secondary storage device

- External schema:

end users → allow data to be customized at the level of individual users or groups

Chapter 2

*The DB design process can be divided to six steps:

1. Requirement elicitation and analysis:-

what data? what operations? what are users?

what is the application built on top of DB?

2. Conceptual DB design: information gathered in the requirement step is used to develop a high-level description

- this step is carried out using the ER model.

- to match how users and developers think of data.

3. Logical DB design:

- Implementation.

- Convert ER design to relational DB scheme

4. Analysis and Refinement

5. physical DB design: Performance, indexing, clustering

6. Application and Security

⇒ Entity - Relationship Model (ER)

- the first step is to build the ER-diagram

Entity: realworld objects distinguishable from others.

Student, Employee, Course

Attributes: the characteristics of entities

Student: ID, name, age, GPA, major

Key: is an attribute or minimal set of attributes whose values uniquely identify an entity

more than one key: candidate keys

- one of them must be primary

③ Relationships: is an association between two or more entities

- Relationships also may have an attribute(s)

Employee works in department since date

* Types of Relationships:

① number of entities

- ① binary
- ② ternary
- ③ n-ary

4 - Unary

* oval → attributes
rectangle → entity

- descriptive attribute: used to record info about a relationship
- many to many (employee works in several depts and depts can have more than one employee)
- one to many (one employee → many depts)

* Key Constraint:

Ex: Assume each department is managed by one employee manager

- An employee can manage more than one department.

thick line: total participation
arrow: one entity

* Relationship Types:

- ① one-to-one: One entity is associated with only one entity

- ② one-to-many: One employee can manage several depts each dep is managed by one manager

③ many-to-many

- each student can enroll many courses,
- course has many students

Ex: each Emp work in one dep and location, a dep can have many locations and emp

* Participation Constraints

① Total: every instance from entity E must participate in relation R

- every course is taught by a lecturer

in ER diagram, total part is denoted by a thick line

* (2) Partial: any part that is not total is partial

Ex:

- each Dep must have one manager
- each Dep must have at least one Emp
- each Employee must work in one Dep
- an Employee can manage many Deps
- the system store the last work date

⇒ Work entity and partial key:-

- the ministry of education make insurance for its emp.
- the insurance can cover the Dependents of every emp.

- Emp is the owner entity for dependent
- DepNo is a partial key
- partial key is an attribute that uniquely identifies a weak entity for a given owner entity.

⇒ Two restrictions with weak entity:

- 1- The owner and weak participate in one-to-many relation
- 2- The weak entity must have total participation
