#### **EQUATION OF STATE**

#### The Ideal-Gas Equation of State

Any equation that relates the pressure, temperature, and specific volume of a substance is called an equation of state.

The simplest and best known equation of state for substances in the gas phase is the *ideal-gas equation of state*.

Gas and vapor are often used as synonymous words. The vapor phase of a substance is called a gas when it is above the critical temperature. Vapor usually implies a gas that is not far from a state of condensation.

It is experimentally observed that at a low pressure the volume of a gas is proportional to its temperature:

$$\begin{cases} P \propto T \\ P \propto \frac{1}{v} & \to P \propto \frac{T}{v} \end{cases}$$

or

Pv = RT

where R is the gas constant. The above equation is called the ideal-gas equation of state (ideal gas relation). Since R is a constant for a gas, one can write:

$$R = \frac{P_1 v_1}{T_1} = \frac{P_2 v_2}{T_2}$$

where subscripts 1 and 2 denote two states of an ideal gas. Note that the constant R is different for each gas; see Tables A1 and A2 in Cengel book.

The ideal gas equation of state can be written in several forms:

$$\begin{cases} V = mv \rightarrow PV = mRT \\ mR = (MN)R = NR_u \rightarrow PV = NR_uT \\ V = N\bar{v} \rightarrow P\bar{v} = R_uT \end{cases}$$

where  $\bar{v} (m^3/kmol)$  is the molar specific volume. That is the volume per unit mole.  $R_u = 8.314 \text{ kJ} / (kmol. K)$  is the universal gas constant,  $R = R_u / M$ .

<u>The molar mass</u> M: is defined as the mass of one mole of a substance (in *gmole* or *kgmol*). The mass of a system is equal to the product of its molar mass M and the mole number N:

$$m = MN$$
 (kg)

See Table A-1 for *R* and *M* for several substances.

An ideal gas is an imaginary substance that obeys the relation Pv = RT. It is experimentally observed that the ideal gas closely approximate the *P*-*v*-*T* behavior of real gases at low densities.

In the range of practical interest, many familiar gases such as air, nitrogen, oxygen, hydrogen, helium, argon, neon, and  $CO_2$  can be treated as ideal gases with negligible error.

<u>Note</u>: Water vapor and refrigerant vapor in refrigerators **should not** be treated as ideal gases.

<u>Note</u>: Water vapor at pressures below 10 kPa can be treated as an ideal gas, regardless of temperature.

#### **Compressibility Factor**

The assumption of ideal gas relation implies that:

- The gas particles take up negligible volume
- The intermolecular potential energy between particles is small
- Particles act independent of one another

However, real gases deviate from ideal gas behavior. This deviation at given temperature and pressure can be accurately accounted for by introduction of a *correction factor* called the compressibility factor Z.

$$Z = \frac{Pv}{RT} \qquad or \qquad Pv = ZRT$$

or  $Z = v_{actual} / v_{ideal} \le 1$ . Obviously, Z = 1 for ideal gases.

Gases behave very much the same at temperatures and pressures normalized with respect to their critical temperatures and pressures.

$$P_R = \frac{P}{P_{cr}}$$
 and  $T_R = \frac{T}{T_{cr}}$ 

Here  $P_R$  and  $T_R$  are called the *reduced pressure* and *temperature*, respectively.

By curve-fitting all the data, the general compressibility chart is obtained which can be used for all gases, see Fig. A-15.

### Uploaded By: Mohammad Awawdeh

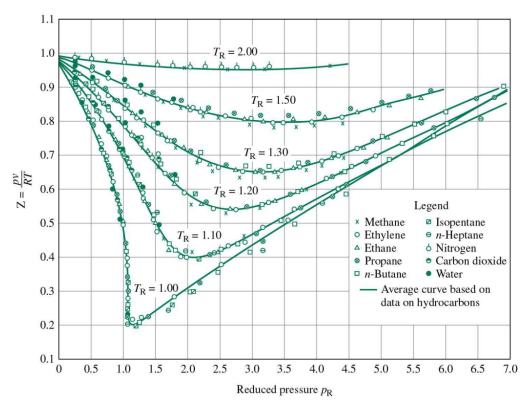

Fig. 6: Z factor, general compressibility chart.

From the Z chart, one can conclude:

- At very low pressure ( $P_R \ll 1$ ), the gases behave as an ideal gas regardless of temperature
- At high temperatures  $(T_R > 2)$ , ideal gas behavior can be assumed.
- The deviation is highest in the vicinity of the critical point.

#### **Example: Ideal Gas**

Determine the specific volume of R-134a at 1 *MPa* and 50°C, using (a) ideal gas equation (b) the generalized compressibility chart. Compare the values obtained with the actual value of  $0.02171 \ m^3/kg$ .

#### Solution:

From Table A-1, for R-134a,  $R = 0.0815 \ kPa.m^3/(kg.K)$ ,  $P_{cr} = 4.067 \ MPa$ , and  $T_{cr} = 374.3 \ K$ 

(a) Ideal gas equation of state

$$v = \frac{RT}{P} = \frac{\left[0.0815 \, kPa.m^3 \, / (kg.K)\right](323 \, K)}{(1000 \, kPa)} = 0.02632 \, m^3 \, / \, kg$$

Comparing with the tabulated value, using ideal gas equation one would get an error of (0.02632-0.02171)/0.02171=0.212 or 21.2%.

(b) To determine the correction factor Z,

$$P_{R} = \frac{P}{P_{cr}} = \frac{1MPa}{4.067MPa} = 0.246$$
$$T_{R} = \frac{T}{T_{cr}} = \frac{323K}{374.3K} = 0.863$$

From Fig. A-15, Z= 0.84. Thus,

$$v = Z v_{ideal} = 0.84 (0.02632 m^3/kg) = 0.02211 m^3/kg$$

The error is less than 2%.

Therefore, in the absence of exact tabulated data, the generalized compressibility chart can be used.

#### **Other Equations of States**

Van der Waals Equation of State:

$$\left(P + \frac{a}{v^2}\right)(v - b) = RT$$

where.

$$a = \frac{27R^2T_{cr}^2}{64P_{cr}}$$
 and  $b = \frac{RT_{cr}}{8P_{cr}}$ 

In this relationship, the intermolecular attraction forces and the volume occupied by molecules are considered.

Note: the accuracy of the Van der Waals equation of state is often inadequate.

#### Beattie-Bridgeman Equation of State

It is based on five experimentally determined constants:

$$P = \frac{R_u T}{\bar{v}^2} \left( 1 - \frac{c}{\bar{v}T^3} \right) \left( \bar{v} + B \right) - \frac{A}{\bar{v}^2}$$

where

$$A = A_0 \left( 1 - \frac{a}{\overline{v}} \right)$$
 and  $B = B_0 \left( 1 - \frac{b}{\overline{v}} \right)$ 

Constants appearing in the above equation are given in Table 3-4, Cengel book.
