

Chapter 4:-

Copper, steel FCC
Iron BCC

Q/RT

$$n_v = n e^{-Q/RT}$$

number of vacancies / cm^3

n :- number of lattice points / atoms / cm^3

Q :- activation Energy

R :- Gas Constant = $1.987 \text{ cal/mol}\cdot\text{K} = 8.314 \text{ J/mol}\cdot\text{K}$

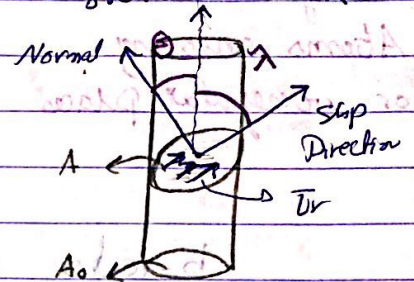

T :- temperature

$n_v \uparrow$ Temp \uparrow

Schmid's law:- $\tau = \sigma \cos \lambda \cos \phi$

$\tau = F/A$ Resolved shear stress

$\sigma = F/A_0$ Unidirectional stress applied on the cylinder

CRSS : to slip, $\text{CRSS} = \tau$

if not make $\text{CRSS} < \tau$

Hall-Petch equation:-

surface defects:-

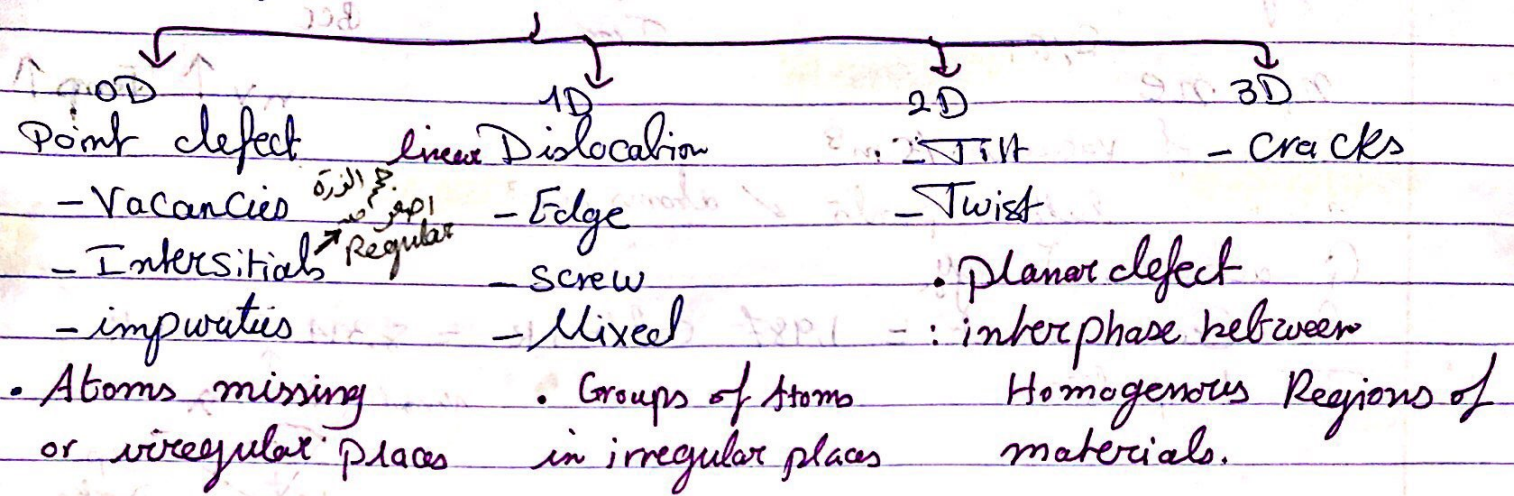

$$\sigma_y = \sigma_0 + K d^{-1/2}$$

yield strength σ_y is equal to σ_0 plus a constant K times the inverse square root of the average diameter of grains d .

Importance of defects:-

⑤

Defect in Solids

b-vector : represents the magnitude & direction of the lattice distortion resulting from a dislocation deformation
