

Chapter 6

Link layer is data transfer between neighboring Network elements (ethernet, wifi, PPP)

↳ frame

↳ link layer transfers datagram from one node to physically adjacent node over a link.

link layer services

- ① framing, link access → datagram to frame (+ header + trailer)
 - ↳ channel access if medium is shared
 - ↳ MAC addresses in frame headers.
- ② reliable delivery between adjacent nodes.
- ③ flow control between adjacent nodes.
- ④ error detection
- ⑤ error correction without retransmission
- ⑥ half-duplex & full duplex
 - both but not at the same time
 - both at the same time.

Host link layer implementation

- in every host. . on chip or NIC . attached to host's system buses
 - . combination of hardware, software, framework.
- EDC : error detection & correction bits. that are added to data.

D	EDC
---	-----

↳ the larger the better
- error detection is not 100% reliable.

parity checking

→ detects single bit errors

receiver

- compute parity of received d.
- compare with received parity bit → if different → error detected.
- * can detect & correct error without retransmission by 2 dimensional parity

internet checksum

→ detect errors (flipped bits) in transmitted segment.

- ~ 16 bit integer of contents of UDP header.
- compute checksum by ones complement sum.
- put value in UDP checksum field & send.
- at receiver compute checksum for received data & compare with received checksum.

Cyclic redundancy check (CRC)

→ more powerful error detection.

D: data G: r+1 bits (generator)

$$\langle D, R \rangle = D \cdot 2^r \oplus R \Rightarrow \text{bits sent.}$$

sender

- ① r = n of bits in G - 1
- ② add 0s as n of r to D
- ③ 
- ④ D ⊕ R → sent checksum
- ⑤ 
- ⑥ if R = 0 ✓ else error detected

MAC Addresses

- | | | |
|-------------------|---|--|
| IP | } | MAC (LAN, Physical, Ethernet address) |
| - network layer | | - link layer |
| - for forwarding | | - to locally get frame from a physically connected interface to another. (same subnet) |
| - 32 bit normally | | - 48 bit burned in NIC ROM & sometimes software settable. |
- * MAC Address allocation administrated by IEEE

ARP (address resolution protocol)

↳ to determine an interface's MAC address from its IP & vice versa.

↳ each IP node on LAN has an ARP table

$\langle \text{IP, MAC, TTL} \rangle$

↳ time after which this mapping will be forgotten
↳ normally 20 min

* in ARP Query \Rightarrow destination MAC FF-FF-FF-FF-FF-FF

↳ if same \rightarrow IP : target IP
subnet

↳ if not destination MAC is router's port.

Ethernet

↳ dominant wired LAN technology. (10 Mbps - 400 Gbps)

↳ simple, cheap, single chip

* physical topology

- bus : in 90s (nodes can collide)

- switched : switches (no collision)

preamble	dest. address	src address	type	data (payload)	CRC
to synch. sender receiver clock rate.	6 byte MAC addresses	indicates higher layer protocol (IP, Novell IPX, AppleTalk) for demuxing	for error detection \rightarrow if detected frame is dropped.		

Cons :

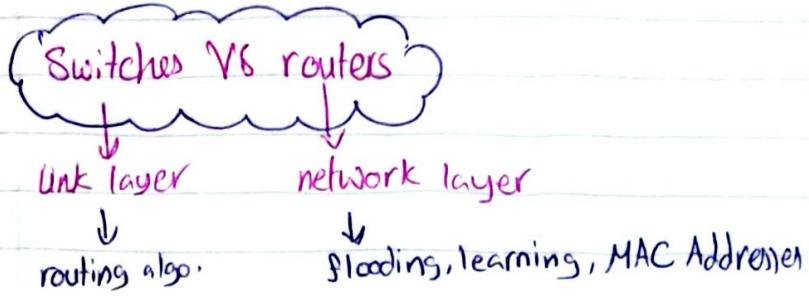

- ↳ connectionless \Rightarrow no Handshaking between NICs.
- ↳ unreliable \Rightarrow no ACKs or NAKs
 - \Rightarrow data in dropped frames can be recovered if sender uses higher layer rdt (TCP)
- ↳ ethernet's MAC protocol is unslotted CSMA/CD with binary backoff.

Switches

- ↳ link layer device
 - ↳ store, forward Ethernet or other frames
 - ↳ transparent \Rightarrow hosts unaware of its presence
 - ↳ plug & play, self learning (no configuration needed)
 - ↳ ethernet protocol on each link \Rightarrow no collisions
 - \Rightarrow full duplex
 - \Rightarrow each link has its collision domain
- * each switch has a { Switch Table }

{ MAC of host, interface to reach host, time stamp }

- * forwarding \Rightarrow ① get incoming link & MAC of sender
- ② record or look for it in table by MAC Destination
- ③ - if destination is same as sender drop frame
- else forward frame to destination.
- else flood

- * multiple VLANs can be configured over single physical LAN.
- * port based VLAN: switch ports grouped so that single physical switch operates as multiple virtual switches
 - frames in VLAN ports can only reach each other
 - dynamic membership: Ports can be dynamically assigned among VLANs.
 - forwarding between VLANs is done via routing
- * trunk port: carries frames between VLANs defined over multiple physical switches.

802.1Q VLAN frame format

→ frames forwarded within VLANs between switches
 can't be 802.1 but 802.1q so it adds/removes
 additional header fields for frames forwarded between
 trunk ports.

preamble	dest address	src address	↓	type	data	CRC
2 byte tag protocol identifier 81-100			↔	↓ tag control info. (12 bit VLAN ID, 3 bit priority field like IP-TOS, 1 bit drop eligible indicator)
