By: Mamoun Nawahdah (Ph.D.) 2022

OO Programming Concepts

- ❖ Object-Oriented Programming (OOP) involves programming using objects.
- ❖ An **object** represents an entity in the world that can be distinctly identified.
- ❖ For example, a *student*, a *desk*, a *circle*, a *button*, and even a *loan* can all be viewed as objects.
- ❖ An object has a unique identity, state, and behaviors.
 - The state of an object consists of a set of data fields (also known as properties) with their current values.

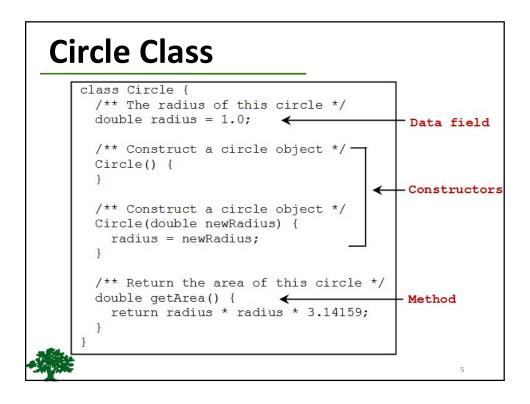

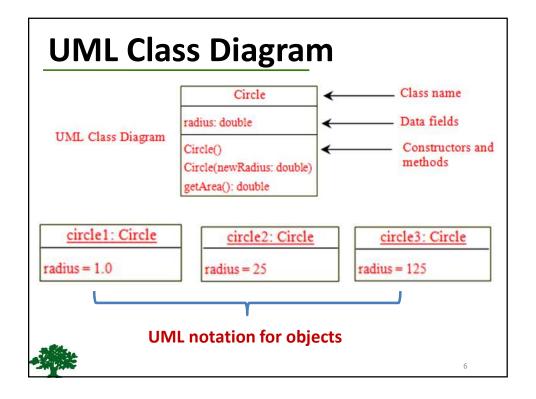

The *behavior* of an object is defined by a set of **methods**.

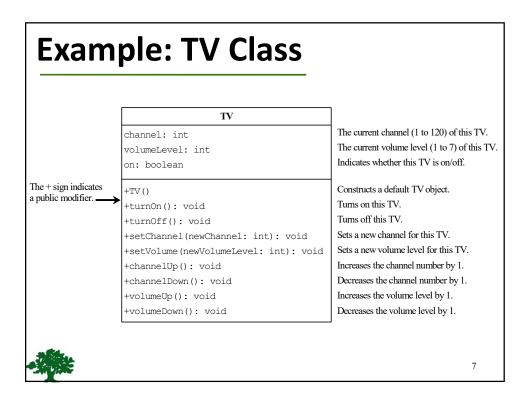

Objects and Classes

- An object has both a state and behavior.
- The state defines the object, and the behavior defines what the object does.
- Classes are constructs that define objects of the same type.
- ❖ A Java class uses *variables* to define data fields and *methods* to define behaviors.
- ❖ Additionally, a class provides a special type of methods, known as **constructors**, which are invoked to construct objects from the class.

Objects and Classes cont. A class template Class Name: Circle Data Fields: radius is Methods: getArea Circle Object 1 Circle Object 2 Circle Object 3 Data Fields: Data Fields: Data Fields: radius is 10 radius is radius is 125 3 objects of the Circle class

Constructors

Constructors are a special kind of methods that are invoked to construct objects.

```
Circle() {
}
Circle(double newRadius) {
   radius = newRadius;
}
```

Constructors cont.

- ❖ A constructor with no parameters is referred to as a **no-arg constructor**.
- ❖ Constructors must have the same name as the class itself.
- ❖ Constructors do not have a return type—not even void.
- ❖ Constructors are invoked using the **new** operator when an object is created.
- Constructors play the role of initializing objects.

9

Creating Objects Using Constructors

new ClassName();

Example:

new Circle();

new Circle(5.0);

Default Constructor

- ❖ A class maybe defined **without** constructors.
- ❖ In this case, a **no-arg constructor** with an empty body is **implicitly** declared in the class.
- This constructor, called a default constructor, is provided automatically

ONLY IF no constructors are **explicitly** defined in the class.

11

Declaring Object Reference Variables

- ❖ To reference an object, assign the object to a reference variable.
- ❖ To declare a reference variable, use the syntax:

ClassName objectRefVar;

Example:

Circle myCircle;

ClassName objectRefVar = new ClassName(); Example: Assign object reference Create an object Circle myCircle = new Circle();

Accessing Object's Members

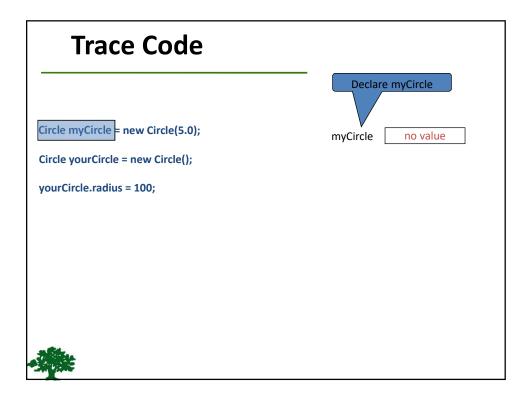

Referencing the object's data: objectRefVar.data

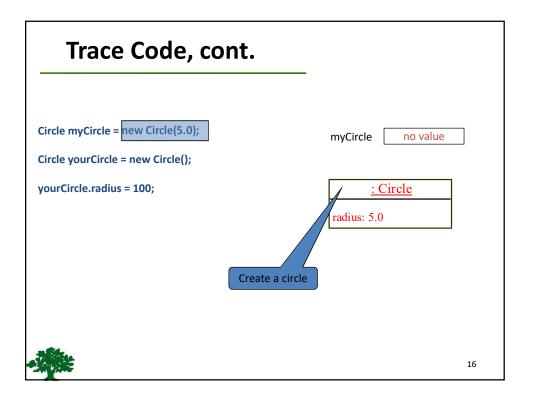

e.g., myCircle.radius

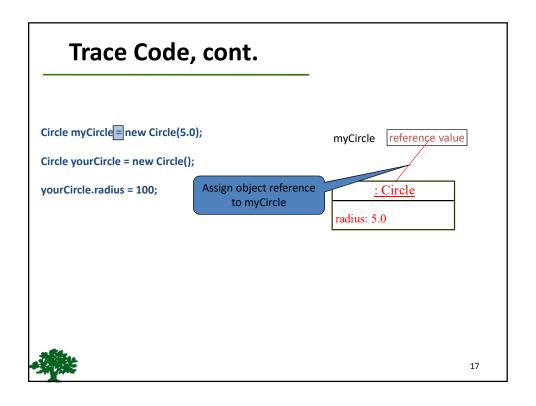

Invoking the object's method: objectRefVar.methodName(arguments)

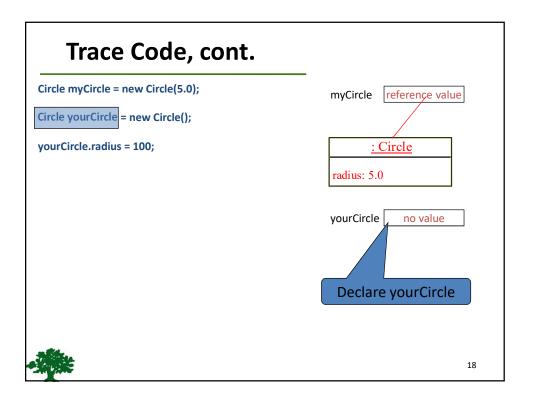

e.g., myCircle.getArea()

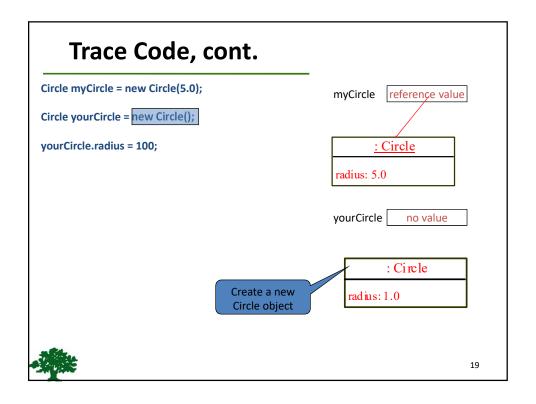

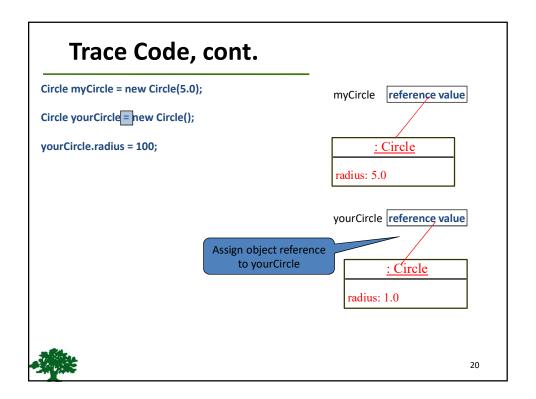

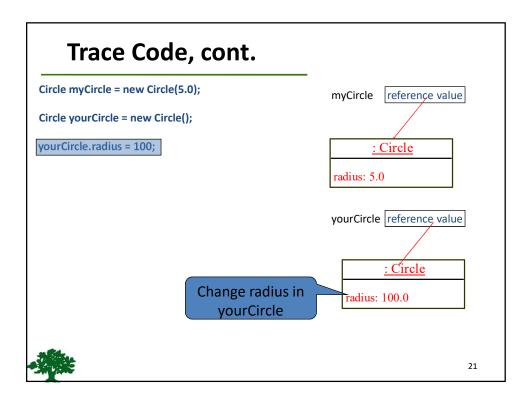

Reference Data Fields

- The data fields can be of reference types.
 - If a data field of a **reference** type does not reference any object, the data field holds a special literal value, **null**.
 - For example, the following **Student** class contains a data field **name** of the **String** type.

```
public class Student {
    String name; // name has default value null
    int age; // age has default value 0
    boolean isScienceMajor; // default false
    char gender; // default value '¥u0000'
}
```

Default Value for a Data Field

❖ The default value of a data field is:

null for a reference type
0 for a numeric type
false for a boolean type
'¥u0000' for a char type

However, Java assigns NO default value to a local variable inside a method.

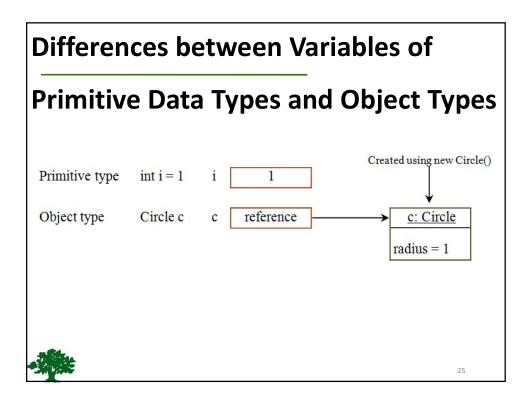

23

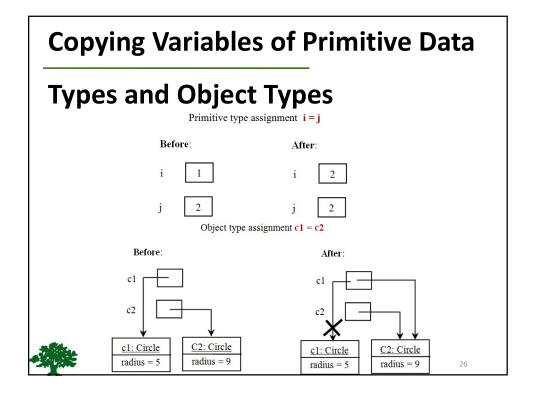

Example

❖ Java assigns no default value to a local variable inside a method.

- 操

Compilation error: variable not initialized

Garbage Collection

- ❖ As shown in the previous figure, after the assignment statement c1 = c2, c1 points to the same object referenced by c2.
- ❖ The object previously referenced by **c1** is no longer referenced.
- ❖ This object is known as **garbage**.
- Garbage is automatically collected by JVM.
- ❖ If you know that an object is no longer needed, you can **explicitly** assign **null** to a reference variable for the object.

27

The **Date** Class

- ❖ Java provides a system-independent encapsulation of date and time in the **java.util.Date** class.
- ❖ You can use the **Date** class to create an instance for the current date and time and use its **toString** method to return the date and time as a **string**.

The Date Class Example

❖ For example, the following code:

```
java.util.Date date = new java.util.Date();
System.out.println( date.toString() );
```

displays a string like:

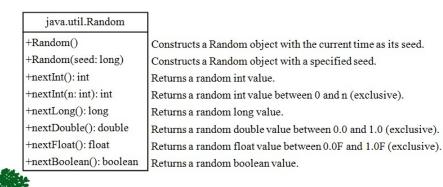

Mon Nov 04 19:50:54 IST 2013

29

The Random Class

- ❖ You have used **Math.random()** to obtain a random **double** value between **0.0** and **1.0** (excluding 1.0).
- ❖ A more useful random number generator is provided in the **java.util.Random** class.

The Point2D Class

Java API has a convenient **Point2D** class in the **javafx.geometry** package for representing a point in a two-dimensional plane.

javafx.geometry.Point2D

+Point2D(x: double, y: double)
+distance(x: double, y: double): double
+distance(p: Point2D): double
+getX(): double
+getY(): double
+toString(): String

Constructs a Point2D object with the specified x- and y-coordinates. Returns the distance between this point and the specified point (x, y). Returns the distance between this point and the specified point p. Returns the x-coordinate from this point. Returns the y-coordinate from this point. Returns a string representation for the point.

31

Instance (Object) Variables, and Methods

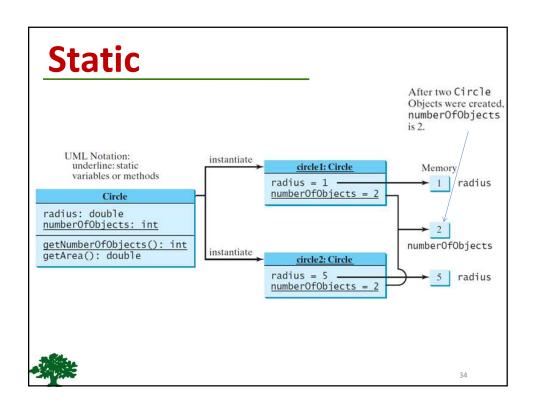

- Instance variables belong to a specific instance (object).
- Instance methods are invoked by an instance (object) of the class.

Static Variables, Constants, and Methods

- ❖ Static variables are shared by all the instances (objects) of the class.
- ❖ Static methods are not tied to a specific instance (object).
- ❖ Static constants are final variables shared by all the instances (objects) of the class.
- ❖ To declare static *variables*, *constants*, and *methods*, use the **Static** modifier.

Static Variable

- It is a variable which belongs to the class and not to the instance (object).
- Static variables are initialized only once, at the start of the execution.
 - Static variables will be initialized first, before the initialization of any instance variables.
- A single copy to be shared by all instances of the class.
- ❖ A static variable can be accessed directly by the class name and doesn't need any object.

Static Method

- ❖ It is a method which **belongs to the class** and **not** to the instance (**object**).
- A static method can access only static data. It can not access non-static data (instance variables).
- A static method can call only other static methods and can not call a non-static method from it.
- A static method can be accessed directly by the class name and doesn't need any object.

Syntax: <class-name>.<static-method-name>(..)

A static method cannot refer to "this" or "super" keywords in anyway.

Note: main method is static, since it must be accessible for an application to run, before any instantiation takes place.

Static example

```
class Student
int a; //initialized to zero
static int b; //initialized to zero only when class is loaded
    //Constructor incrementing static variable b
   public void showData(){
   System.out.println("Value of a = "+a);
   System.out.println("Value of b = "+b);
//public static void increment(){
   public static void main(String args[]){
      Student s1 = new Student();
      s1.showData();
                                                      C:\WINDOWS\system32\cmd.ex
      Student s2 = new Student();
                                                        \workspace>java Demo
lue of a = Ø
lue of b = 1
      s2.showData();
                                                      Value of a
Value of b
Value of a
Value of a
      //Student.b++
      //s1.showData();
```

Visibility Modifiers

- * By default (when no visibility modifiers are used), the *class*, *variable*, or *method* can be accessed by any class in the same package.
- public modifier: The class, data, or method is visible to any class in any package.
- private modifier: The data or method can be accessed only by the declaring class.
 - The get and set methods are used to read and modify private properties.

```
package p1;
public class C1 {
   public int x;
   int y;
   private int z;

public void m1() {
   }
   void m2() {
   }
   private void m3() {
   }
}
```

```
package p1;

public class C2 {
    void aMethod() {
        C1 o = new C1();
        can access o.x;
        can access o.y;
        cannot access o.z;

        can invoke o.m1();
        can invoke o.m2();
        cannot invoke o.m3();
    }
}
```

```
package p2;

public class C3 {
   void aMethod() {
    C1 o = new C1();
    can access o.x;
   cannot access o.y;
   cannot access o.z;

   can invoke o.m1();
   cannot invoke o.m2();
   cannot invoke o.m3();
  }
}
```

- The private modifier restricts access to within a class,
- the default modifier restricts access to within a package,
- and the public modifier enables unrestricted access.

39

```
package p1;
class C1 {
    ...
}
```

```
package p1;
public class C2 {
  can access C1
}
```

```
package p2;
public class C3 {
   cannot access C1;
   can access C2;
}
```

- The default modifier on a class restricts access to within a package,
- access.

NOTE

❖ An object **cannot** access its private members, as shown in (**b**). It is OK, however, if the object is declared in its own class, as shown in (**a**).

```
public class C {
  private boolean x;

public static void main(String[] args) {
    C c = new C();
    System.out.println(c.x);
    System.out.println(c.convert());
}

private int convert() {
    return x ? 1 : -1;
}

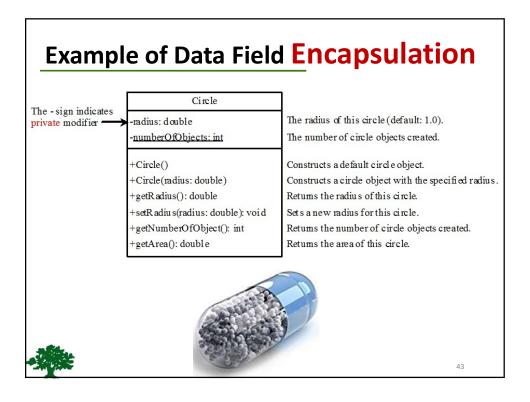

(a) This is okay because object c is used inside the class C.
```

```
public class Test {
  public static void main(String[] args) {
    C c = new C();
    System.out.println(c.x);
    System.out.println(c.convert());
  }
}
(b) This is wrong because x and convert are private in class C.
```

Why Data Fields Should Be private?

- ❖ To protect data.
- ❖ To make code easy to maintain.

Overloading Methods/Constructors

- In a class, there can be several methods with the same name. However they must have different signature.
- The signature of a method is comprised of its name, its parameter types and the order of its parameter.
- The signature of a method is **not** comprised of its *return type* nor *its visibility* nor its *thrown exceptions*.

Passing Objects to Methods

- Passing by value for primitive type value:
 - The **value** is passed to the parameter
- **Passing by reference** for reference type value:
 - The value is the **reference** to the object

Passing Objects to Methods

```
public class TestPassObject {
 public static void main(String[] args) {
     Circle myCircle = new Circle(1);
    // Print areas for radius 1, 2, 3, 4, and 5.
    int n = 5;
    printAreas(myCircle, n);
    System.out.println("\n" + "Radius is " + myCircle.getRadius());
    System.out.println("n is" + n);
 /** Print a table of areas for radius */
 public static void printAreas (Circle c, int times) {
  System.out.println("Radius \t\tArea");
  while (times >= 1) {
       System.out.println(c.getRadius() + "\t^{+} c.getArea());
      c.setRadius(c.getRadius() + 1);
       times--;
```

Immutable Objects and Classes

If the contents of an object (instance)
can't be changed once the object is
created, the object is called an

immutable object and its class is called an immutable class.

47

Immutable Objects and Classes

If you delete the set method in the Circle class, the class would be

immutable

because **radius** is private and cannot be changed without a **set** method.

```
public class Circle {
  private double radius = 1;

public double getArea() {
  return radius * radius * Math.PI;
 }

public void setRadius(double r) {
  radius = r;
 }
}
```

- 漢族

Immutable Objects and Classes

- A class with all private data fields and without set methods is not necessarily immutable.
- ❖ For example, the following class **Student** has all **private** data fields and no **set** methods, but it is mutable!!!

```
Example
                           public class Student {
                            private int id;
                            private java.util.Date birthDate;
                            public Student(int ssn, Date newBD) {
                               id = ssn:
                               birthDate = newBD;
                             }
                             public int getId() {
                                                  return id; }
                             public Date getBirthDate() { return birthDate; }
         public class Test {
           public static void main(String[] args) {
             java.util.Date bd = new java.util.Date();
             Student student = new Student(111223333, bd);
             java.util.Date date = student.getBirthDate();
             date.setMonth(5); // Now the student birthdate is changed!
```

What Class is Immutable?

- For a class to be immutable:
 - It must mark all data fields private.
 - Provide no set methods.
 - No **get** methods that would return a reference to a mutable data field object.

51

Scope of Variables

- The scope of instance (object) and static variables is the entire class. They can be declared anywhere inside a class.
- ❖ The scope of a local variable starts from its declaration and continues to the end of the block that contains the variable.
- A local variable **must** be initialized explicitly before it can be used.

Scope of Variables

❖ What is the output?

```
public class A {
  int year = 2020; // instance variable
  void p() {
    System.out.println("Year: "+ year);
    int year = 2021; // local variable
    System.out.println("Year: "+ year);
  }
}

public class B {
  public static void main (String[] s) {
    A a = new A();
    a.p();
  }
}
```

The this Keyword

- The this keyword is the name of a reference that refers to an **object itself**.
- One common use of the this keyword is reference a class's hidden data fields.
- Another common use of the this keyword to enable a constructor to invoke another constructor of the same class.

Reference the Hidden Data Fields

```
public class F {
    private int i = 5;
    private static double k = 0;
    void setI(int i) {
        this.i = i;
    }
    static void setK(double k) {
        F.k = k;
    }
}

Suppose that f1 and f2 are two objects of F.
    F f1 = new F(); F f2 = new F();

Invoking f1.setI(10) is to execute
    this.i = 10, where this refers f1

Invoking f2.setI(45) is to execute
    this.i = 45, where this refers f2
```

Calling Overloaded Constructor

```
public class Circle {
    private double radius;
    public Circle(double radius) {
        this.radius = radius;
    }
        this must be explicitly used to reference the data field radius of the object being constructed public Circle() {
        this(1.0);
    }
        this is used to invoke another constructor public double getArea() {
        return this.radius * this.radius * Math.PI;
    }
}

Every instance variable belongs to an instance represented by this, which is normally omitted
```
