VI. VISCOUS INTERNAL FLOW

To date, we have considered only problems where the viscous effects were either:

- a. known: i.e. known F_D or hf
- b. negligible: i.e. inviscid flow

This chapter presents methodologies for predicting viscous effects and viscous flow losses for internal flows in pipes, ducts, and conduits.

Typically, the first step in determining viscous effects is to determine the flow regime at the specified condition.

The two possibilities are:

- a. Laminar flow
- b. Turbulent flow

The student should read Section 6.1 in the text, which presents an excellent discussion of the characteristics of laminar and turbulent flow regions.

For steady flow at a known flow rate, these regions exhibit the following:

Laminar flow:	A local velocity constant with time, but which varies spatially due to viscous shear and geometry.
Turbulent flow:	A local velocity which has a constant mean value but also has a statistically random fluctuating component due to turbulence in the flow.

Typical plots of velocity time histories for laminar flow, turbulent flow, and the region of transition between the two are shown below.

Fig. 6.1 (a) Laminar, (b)transition, and (c) turbulent flow velocity time histories.

STUDENTS-HUB.com

Principal parameter used to specify the type of flow regime is the

Reynolds number - Re =
$$\frac{\rho VD}{\mu} = \frac{VD}{v}$$

V - characteristic flow velocity D - characteristic flow dimension μ - dynamic viscosity υ - kinematic viscosity = $\frac{\mu}{\rho}$

We can now define the

 $Re_{cr} \equiv$ critical or transition Reynolds number

 $Re_{cr} \equiv Reynolds$ number below which the flow is laminar, above which the flow is turbulent

While transition can occur over a range of Re, we will use the following for internal pipe or duct flow:

$$\operatorname{Re}_{\operatorname{cr}} \cong 2300 = \frac{\rho \operatorname{VD}}{\mu}_{\operatorname{cr}} = \frac{\operatorname{VD}}{\upsilon}_{\operatorname{cr}}$$

Internal Viscous Flow

A second classification concerns whether the flow has significant entrance region effects or is fully developed. The following figure indicates the characteristics of the entrance region for internal flows. Note that the slope of the streamwise pressure distribution is greater in the entrance region than in the fully developed region.

Typical criteria for the length of the entrance region are given as follows:

Laminar:

$$\frac{L_e}{D} \cong 0.06 \,\mathrm{Re}$$

STUDENTS-HUB.com

Turbulent
$$\frac{L_e}{D} \cong 4.4 \text{Re}^{1/6}$$

where: $L_e =$ length of the entrance region

Note: Take care in neglecting entrance region effects.

In the entrance region, frictional pressure drop/length > the pressure drop/length for the fully developed region. Therefore, if the effects of the entrance region are neglected, the overall predicted pressure drop will be low. This can be significant in a system with short tube lengths, e.g., some heat exchangers.

Fully Developed Pipe Flow

The analysis for **steady, incompressible, fully developed, laminar flow** in a circular horizontal pipe yields the following equations:

$$U(r) = -\frac{R^2}{4\mu} \frac{dP}{dx} \left\{ 1 - \frac{r^2}{R^2} \right\}$$

STUDENTS-HUB.com

$$\frac{U}{U_{\text{max}}} = \left\{ 1 - \frac{r^2}{R^2} \right\} \quad , \quad U_{\text{max}} = 2V_{avg}$$

and

$$\mathbf{Q} = \mathbf{A} \mathbf{V}_{avg} = \boldsymbol{\pi} \mathbf{R}^2 \mathbf{V}_{avg}$$

Key Points: Thus for laminar, fully developed pipe flow (not turbulent):

- a. The velocity profile is parabolic.
- b. The maximum local velocity is at the centerline (r = 0).
- c. The average velocity is one-half the centerline velocity.
- d. The local velocity at any radius varies only with radius, not on the streamwise (x) location (due to the flow being fully developed).

Note: All subsequent equations will use the symbol V (no subscript) to represent the average flow velocity in the flow cross section.

Darcy Friction Factor:

We can now define the Darcy friction factor f as:

where ΔP_f = the pressure drop due to <u>friction</u> only.

The general energy equation must still be used to determine total pressure drop.

Therefore, we obtain

$$\Delta P_f = \rho g h_f = f \frac{L}{D} \rho \frac{V^2}{2}$$

and the friction head loss h_f is given as

$$h_f = f \frac{L}{D} \frac{V}{2g}^2$$

Note: The definitions for f and h_f are <u>valid for either laminar or turbulent flow</u>. However, you must evaluate f for the correct flow regime, laminar or turbulent.

VI-4

STUDENTS-HUB.com

Key Point: It is common in industry to define and use a "<u>fanning</u>" friction factor f_f . The fanning friction factor differs from the Darcy friction factor by a factor of 4. Thus, care should be taken when using unfamiliar equations or data since use of f_f in equations developed for the Darcy friction factor will result in significant errors (a factor of 4). Your employer will not be happy if you order a 10 hp motor for a 2.5 hp application. The equation suitable for use with $f_f I s$

$$h_f = 4 f_f \frac{L}{D} \frac{V^2}{2g^2}$$

Laminar flow:

Application of the results for the laminar flow velocity profile to the definition of the Darcy friction factor yields the following expression:

- -

$$f = \frac{64}{\text{Re}}$$
 laminar flow only (**Re** < 2300)

Thus with the value of the Reynolds number, the friction factor for laminar flow is easily determined.

Turbulent flow:

A similar analysis is not readily available for turbulent flow. However, the Colebrook equation, shown below, provides an excellent representation for the variation of the Darcy friction factor in the turbulent flow regime. Note that the equation depends on both the pipe Reynolds number and the roughness ratio, is transcendental, and cannot be expressed explicitly for f.

$$f = -2\log\left[\frac{2.51}{\text{Re }f^{1/2}} + \frac{\varepsilon/D}{3.7}\right]$$

turbulent flow only (**Re** > **2300**)

STUDENTS-HUB.com

where $\mathbf{\mathcal{E}} =$ nominal roughness of pipe or duct being used. (Table 6.1, text) (Note: Take care with units for $\mathbf{\mathcal{E}}$; $\mathbf{\mathcal{E}}$ /D must be non-dimensional).

A good approximate equation for the turbulent region of the Moody chart is given by Haaland's equation:

$$f = \left\{-1.8\log\left[\frac{6.9}{\text{Re}} + \left(\frac{\varepsilon/D}{3.7}\right)^{1.11}\right]\right\}^{-2}$$

Note again the roughness ratio \mathcal{E}/D must be non-dimensional in both equations. Graphically, the results for both laminar and turbulent flow pipe friction are represented by the Moody chart as shown below.

Typical roughness values are shown in the following table:

VI-6

STUDENTS-HUB.com

Table 6.1 Average roughness values of commercial pipe

Haaland's equation is valid for turbulent flow (Re > 2300) and is easily set up on a computer, spreadsheet, etc.

Key fluid system design considerations for laminar and turbulent flow

- **a.** Most internal flow problems of engineering significance are turbulent, not laminar. Typically, a very low flow rate is required for internal pipe flow to be laminar. If you open your kitchen faucet and the outlet flow stream is larger than a kitchen match, the flow is probably turbulent. Thus, check your work carefully if your analysis indicates laminar flow.
- **b**. The following can be easily shown:

Laminar flow:

$$\begin{split} \Delta P_{f} &\sim \left\{ \mu, L, Q, D^{-4} \right\} \\ \dot{W}_{f} &\sim \left\{ \mu, L, Q^{2}, D^{-4} \right\} \\ \Delta P_{f} &\sim \left\{ \rho^{3/4}, \mu^{1/4}, L, Q^{1.75}, D^{-4.75} \right\} \end{split}$$

Turbulent flow:

$$\dot{W}_{f} \sim \left\{ \rho^{_{3/4}}, \mu^{_{1/4}}, L, Q^{_{2.75}}, D^{_{4.75}} \right\}$$

Thus both pressure drop and pump power are <u>very dependent</u> on flow rate and pipe/conduit diameter. Small changes in diameter and/or flow rate can significantly change circuit pressure drop and power requirements.

STUDENTS-HUB.com

Example (Laminar flow):

Water, 20°C flows through a 0.6 cm tube, 30 m long, at a flow rate of 0.34 liters/min. If the pipe discharges to the atmosphere, determine the supply pressure if the tube is inclined 10° above the horizontal in the flow direction.

Water Properties:

$$\rho = 998 \text{ kg/m}^3 \quad \rho g = 9790 \text{ N/m}^3$$

$$v = 1.005 \text{ E-6 m}^2/\text{s}$$

which for steady-flow in a constant diameter pipe with $P_2 = 0$ gage becomes,

$$\frac{P_1}{\rho g} = Z_2 - Z_1 + h_f = L \sin 10^\circ + h_f$$

 $\frac{P_1 - P_2}{\rho g} = \frac{V_2^2 - V_1^2}{2 g} + Z_2 - Z_1 + h_f - h_p$

Energy Equation

$$V = \frac{Q}{A} = \frac{0.34E^{-3} m^3 / \min^* 1 \min/ 60 s}{\pi (0.3 / 100)^2 m^2} = 0.2 m / s$$

$$\operatorname{Re} = \frac{VD}{v} = \frac{0.2 * 0.006}{1.005 E^{-6}} = 1197 \rightarrow \text{laminar flow}$$

$$f = \frac{64}{Re} = \frac{64}{1197} = 0.0535$$

$$h_f = f \frac{L}{D} \frac{V^2}{2g} = 0.0535 * \frac{30m}{0.006m} \frac{0.2^2}{2*9.807m/s^2} = 0.545m$$

$$\frac{P_1}{\rho g} = 30 * \sin 10P + 0.545 = 5.21 + 0.545 = 5.75m$$
gravity friction total head head loss

head head loss $P_1 = 9790 \text{ N/m}^3 \times 5.75 \text{ m} = 56.34 \text{ kN/m}^3 \text{ (kPa)} \sim 8.2 \text{ psig}$ ans.

VI-8

STUDENTS-HUB.com

Example: (turbulent flow)

Oil, $\rho = 900 \text{ kg/m}^3$, $\nu = 1 \text{ E-5 m}^2/\text{s}$, flows at 0.2 m³/s through a 500 m length of 200 mm diameter, cast iron pipe. If the pipe slopes downward 10° in the flow direction, compute hf, total head loss, pressure drop, and power required to overcome these losses.

The energy equation can be written as follows where $h_t = total head$ loss.

$$\frac{P_1 - P_2}{\rho g} = h_t = \frac{V_2^2 - V_1^2}{2g} + Z_2 - Z_1 + h_f - h_p$$

which reduces to

$$h_t = Z_2 - Z_1 + h_f$$

$$V = \frac{Q}{A} = \frac{0.2 \, m^3 \, / \, s}{\pi (.1)^2 \, m^2} = 6.4 \, m \, / \, s \qquad \text{Table 6.1, cast iron, } \mathbf{\epsilon} = 0.26 \, \text{mm}$$

Re = $\frac{VD}{v} = \frac{6.4 * .2}{1E^{-5}} = 128,000 \rightarrow \text{turbulent flow}, \qquad \frac{\mathcal{E}}{D} = \frac{0.26}{200} = 0.0013$

Since flow is turbulent, use Haaland's equation to determine friction factor (check your work using the Moody chart).

$$f = \left\{-1.8\log\left[\frac{6.9}{\text{Re}} + \left(\frac{\mathcal{E}/D}{3.7}\right)^{1.11}\right]\right\}^{-2}, f = \left\{-1.8\log\left[\frac{6.9}{128,000} + \left(\frac{0.0013}{3.7}\right)^{1.11}\right]\right\}^{-2}$$
$$f = 0.02257 \quad h_f = f\frac{L}{D}\frac{V^2}{2g} = 0.02257 * \frac{500m}{0.2m}\frac{6.4^2}{2*9.807m/s^2} = 116.6m \quad \text{ans.}$$
$$h_t = Z_2 - Z_1 + h_f = -500 \sin^0 + 116.6 = -86.8 + 116.6 = 29.8 \text{ m} \quad \text{ans.}$$

STUDENTS-HUB.com

Note that for this problem, there is a negative gravity head loss (i.e. a head increase) and a positive frictional head loss resulting in the net head loss of 29.8 m.

$$\Delta P = \rho g h_t = 900 kg / m^3 * 9.807 m / s^2 * 29.8 m = 263 kPa$$
 ans.

$$\dot{W} = \rho Qg h_t = Q\Delta P = 0.2 m^3 / s^* 273,600 N / m^2 = 54.7 kw$$
 ans.

Note that this is not necessarily the power required to drive a pump, as the pump efficiency will typically be less than 100%.

These problems are easily set up for solution in a spreadsheet as shown below. Make sure that the calculation for friction factor includes a test for laminar or turbulent flow with the result proceeding to the correct equation.

Always verify any computer solution with problems having a known solution.

FRICTIONAL HEAD LOSS CALCULATION

VI-10

STUDENTS-HUB.com

Solution Summary:

To solve basic pipe flow frictional head loss problem, use the following procedure:

- 1. Use known flow rate to determine Reynolds number.
- 2. Identify whether flow is laminar or turbulent.
- 3. Use appropriate expression to determine friction factor (w \mathcal{E}/D if necessary).
- 4. Use definition of hf to determine friction head loss.
- 5. Use general energy equation to determine total pressure drop.

Unknown Flow Rate and Diameter Problems

Problems involving unknown flow rate and diameter in general require iterative/ trial & error solutions due to the complex dependence of Re, friction factor, and head loss on velocity and pipe size.

Unknown Flow Rate:

For the special case of known friction loss hf a closed form solution can be obtained for the problem of unknown Q.

The solution proceeds as follows:

Given: Known values for D, L, h_f , ρ , and μ calculate V or Q.

Define solution parameter:

$$\varsigma = \frac{1}{2} f \operatorname{Re}_D^2 = \frac{g D^3 h_f}{L v^2}$$

Note that this solution does not contain velocity and the parameter ζ can be calculated from known values for D, L, h_f, ρ , and μ . The Reynolds number and subsequently the velocity can be determined from ζ and the following equations:

Turbulent:
$$\operatorname{Re}_{D} = -\left(8\zeta\right)^{1/2} \log\left\{\frac{\varepsilon/D}{3.7} + \frac{1.775}{\sqrt{\zeta}}\right\}$$

STUDENTS-HUB.com

$$\operatorname{Re}_{D} = \frac{\varsigma}{32}$$

and laminar to turbulent transition can be assumed to occur approximately at $\zeta = 73,600$ (check Re at end of calculation to confirm).

Note that this procedure is not valid (except perhaps for initial estimates) for problems involving significant minor losses where the head loss due only to pipe friction is not known.

For these problems a trial and error solution using a computer is best.

Example 6.9

Oil, with $\rho = 950 \text{ kg/m}^3$ and $\nu = 2 \text{ E-5 m}^2/\text{s}$, flows through 100 m of a 30 cm diameter pipe. The pipe is known to have a head loss of 8 m and a roughness ratio $\epsilon/D = 0.0002$. Determine the flow rate and oil velocity possible for these conditions.

Without any information to the contrary, we will neglect minor losses and KE head changes. With these assumptions, we can write:

$$\varsigma = \frac{g D^3 h_f}{L v^2} = \frac{9.807 \, m / s^2 * 0.30^3 \, m^3 * 8.0 \, m}{100 \, m * \left(2 \, E - 5 \, m^2 / s\right)^2} = 5.3 \, E7 > 73,600; \text{ turbulent}$$

$$\operatorname{Re}_{D} = -\left(8*5.3\,E7\right)^{1/2} \log\left\{\frac{0.0002}{3.7} + \frac{1.775}{\sqrt{5.3\,E7}}\right\} = 72,600 \quad \operatorname{checks, turbulent}$$

$$\operatorname{Re}_{D} = \frac{VD}{v}, \quad V = \frac{72,600*2E - 5m^{2}/s}{0.3m} = 4.84\frac{m}{s}$$
 ans.

 $Q = AV = \pi .15^2 \text{ m}^2 4.84 \text{ m/s} = 0.342 \text{ m}^3/\text{s}$ ans.

This is the maximum flow rate and oil velocity that could be obtained through the given pipe and given conditions (hf = 8 m).

VI-12

STUDENTS-HUB.com

Note that this problem could have also been solved using a computer based trial and error procedure in which a value is assumed for the fluid flow rate until a flow rate is found which results in the specified head loss. Note also that with this procedure, the problem being solved can include the effects of minor losses, KE, and PE changes with no additional difficulty.

Unknown Pipe Diameter:

A similar difficulty arises for problems involving unknown pipe difficulty, except a closed form, analytical solution is not available. Again, a trial and error solution is appropriate for use to obtain the solution and the problem can again include losses due to KE, PE, and piping components with no additional difficulty.

Non-Circular Ducts:

For flow in non-circular ducts or ducts for which the flow does not fill the entire cross-section, we can define the hydraulic diameter D_h as

$$D_h = \frac{4A}{P}$$

where

A = cross-sectional area of actual flow,

P = wetted perimeter, i.e. the perimeter on which viscous shear acts

Perimeter - P

With this definition, <u>all previous equations</u> for the Reynolds number Re friction factor f and head loss h_f are valid as previously defined and can be used on both circular and non-circular flow cross sections.

Minor Losses

In addition to frictional losses for a length L of pipe, we must also consider losses due to various fittings (valves, unions, elbows, tees, etc.). These losses are expressed as

$$h_m = K_i \frac{V^2}{2g}$$

STUDENTS-HUB.com

where

 h_m = the equivalent head loss across the fitting or flow component.

V = average flow velocity for the pipe size of the fitting

 K_i = the minor loss coefficient for given flow component; valve, union, etc. See Sec. 6.7, Table 6.5, 6.6, Fig. 6.19, 6.20, 6.21, 6.22, etc.

Table 6.5 shows minor loss K values for several common types of valves, fully open, and for elbows and tees.

Table 6.5 Minor loss coefficient for common valves and piping components

Swing check	5.1	2.9	2.1	2.0	2.0	2.0	2.0	2.0	2.0
Angle	9.0	4.7	2.0	1.0	4.5	2.4	2.0	2.0	2.0
Elbows:									
45° regular	0.39	0.32	0.30	0.29					
45° long radius					0.21	0.20	0.19	0.16	0.14
90° regular	2.0	1.5	0.95	0.64	0.50	0.39	0.30	0.26	0.2
90° long radius	1.0	0.72	0.41	0.23	0.40	0.30	0.19	0.15	0.10
180 ^a regular	2.0	1.5	0.95	0.64	0.41	0.35	0.30	0.25	0.20
180° long radius					0.40	0.30	0.21	0.15	0.10
Tees:									
Line flow	0.90	0.90	0.90	0.90	0.24	0.19	0.14	0.10	0.0
Branch flow	2.4	1.8	1.4	1.1	1.0	0.80	0.64	0.58	0.4

Figure 6.18 shows minor loss K values for several types of common valves.

Note that the K valves shown here are for the indicated fractional opening. Also, fully open values may not be consistent with values indicated in Table 6.5 for fully open valves or for the valve of a particular manufacturer. In general, use specific manufacturer's data when available.

STUDENTS-HUB.com

Fig. 6.18 Average loss coefficients for partially open valves

Note that exit losses are K \cong 1 for all <u>submerged</u> exits, e.g., fluid discharged into a tank at a level below the fluid surface.

Also, for an open pipe discharge to the atmosphere, there is no loss coefficient when the energy equation is written only to the end of the pipe.

In general, do not take point 1 for an analysis to be in the plane of an inlet having an inlet loss. You do not know what fraction of the inlet loss to consider.

Fig. 6.21 Entrance and exit loss coefficients(a) reentrant inlets; (b) rounded and beveled inlets

STUDENTS-HUB.com

Fig. 6.22 Sudden contraction and expansion losses.

Note that the losses shown in Fig. 6.22 do not represent losses associated with pipe unions or reducers. These must be found in other sources in the literature.

Also note that the loss coefficient is always based on the velocity in the smaller diameter (d) of the pipe, irrespective of the direction of flow.

Assume that this is also true for reducers and similar area change fittings.

These and other sources of data now provide the ability to determine frictional losses for both the pipe and other piping/duct flow components.

The total frictional loss now becomes

$$h_f = f \frac{L}{D} \frac{V^2}{2g^2} + \sum K_i \frac{V^2}{2g}$$

or

$$h_f = \left\{ f \frac{L}{D} + \sum K_i \right\} \frac{V^2}{2g}$$

These equations would be appropriate for a single pipe size (with average velocity V). For multiple pipe/duct sizes, this term must be repeated for each pipe size.

Key Point: The energy equation must still be used to determine <u>the total head</u> <u>loss and pressure drop</u> from all possible contributions.

VI-16

STUDENTS-HUB.com

Example 6.16

Water, $\rho = 1.94$ slugs/ft³ and $\nu = 1.1$ E-5 ft²/s, is pumped between two reservoirs at 0.2 ft³/s through 400 ft of 2–in diameter pipe with $\epsilon/D = 0.001$ having the indicated minor losses. Compute the pump horsepower (motor size) required.

Writing the energy equation between points 1 and 2 (the free surfaces of the two reservoirs), we obtain

$$\frac{P_1 - P_2}{\rho g} = \frac{V_2^2 - V_1^2}{2g} + Z_2 - Z_1 + h_f - h_p$$

For this problem, the pressure $(P_1 = P_2)$ and velocity $(V_1 = V_2 = 0)$ head terms are zero and the equation reduces to

$$h_p = Z_2 - Z_1 + h_f = Z_2 - Z_1 + \left\{ f \frac{L}{D} + \sum K_i \right\} \frac{V^2}{2g^2}$$

For a flow rate Q = 0.2 ft³/s we obtain

VI-17

STUDENTS-HUB.com

$$V = \frac{Q}{A} = \frac{0.2 \ ft^3 \ / \ s}{\pi (1/12)^2 \ ft^2} = 9.17 \ ft \ / \ s$$

With
$$\epsilon/D = 0.001$$
 and $\text{Re} = \frac{VD}{V} = \frac{9.17 \text{ ft}/\text{s}(2/12) \text{ ft}}{1.1E - 5 \text{ ft}^2/\text{s}} = 139,000$

the flow is turbulent and Haaland's equation can be used to determine the friction factor:

$$f = \left\{-1.8\log\left[\frac{6.9}{139,000} + \left(\frac{.001}{3.7}\right)^{1.11}\right]\right\}^{-2} = 0.0214$$

the minor losses for the problem are summarized in the following table:

Note: The loss for a pipe bend is not the same as for an elbow fitting.

If there were no tank at the pipe discharge and point 2 were at the pipe exit, there would be no exit loss coefficient. However, there would be an exit K.E. term.

Loss element	Ki
Sharp entrance (Fig. 6.21)	0.5
Open globe valve (Table 6.5)	6.9
12 " bend, R/D = 12/6 = 2 (Fig. 6.19)	0.15
Threaded, 90Þ, reg. elbow, (Table 6.5)	0.95
Gate valve, 1/2 closed (Fig. 6.18)	2.7
Submerged exit (Fig. 6.20)	1
Ki =	12.2

Substituting in the energy equation we obtain

$$h_{p} = (120 - 20) + \left\{ 0.0214 \frac{400}{2/12} \frac{9.17^{2}}{64.4} \right\} + \left\{ 12.2 \frac{9.17^{2}}{64.4} \right\}$$

$$h_p = 100 + 67.1 + 15.9 = 183 \text{ ft}$$

VI-18

STUDENTS-HUB.com

Note the distribution of the total loss between static, pipe friction, and minor losses.

The power required to be delivered to the fluid is give by

$$P_{\rm f} = \rho Qgh_p = 1.94 \frac{slug}{ft^3} 32.2 \frac{ft}{s^2} 0.2 \frac{ft^3}{s} 183 \, ft = 2286 \, ft \, lbf$$
$$P_{\rm f} = \frac{2286 ft \, lbf}{550 ft \, lbf/s/hp} = 4.2 hp$$

If the pump has an efficiency of 70 %, the power requirements would be specified by

$$\dot{W}_{p} = \frac{4.2 \, hp}{0.70} = 6 \, hp$$

Solution Summary:

To solve basic pipe flow pressure drop problem, use the following procedure:

- 1. Use known flow rate to determine Reynolds number.
- 2. Identify whether flow is laminar or turbulent.
- 3. Use appropriate expression to find friction factor (with \mathcal{E}/D if necessary).
- 4. Use definition of h_f to determine friction head loss.
- 5. Tabulate and sum minor loss coefficients for piping components.
- 6a. Use general energy equation to determine total pressure drop, or
- 6b.Determine pump head requirements as appropriate.
- 7. Determine pump power and motor size if required.

Multiple-Pipe Systems

Basic concepts of pipe system analysis apply also to multiple pipe systems. However, the solution procedure is more involved and can be iterative.

Consider the following:

- a. Multiple pipes in series
- b. Multiple pipes in parallel

Series Pipe System:

The indicated pipe system has a steady flow rate Q through three 1 2 3 pipes with diameters D₁, D₂, & D₃. a b

Two important rules apply to this problem.

1. The flow rate is the same through each pipe section. For incompressible flow, this is expressed as

$$Q_1 = Q_2 = Q_3 = Q$$
 or $D_1^2 V_1 = D_2^2 V_2 = D_3^2 V_3$

2. The total frictional head loss is the sum of the head losses through the various sections.

$$h_{f,a-b} = h_{f,1} + h_{f,2} + h_{f,3}$$

$$h_{f,a-b} = \left(f\frac{L}{D} + \sum K_i\right)_{D_1} \frac{V_1^2}{2g} + \left(f\frac{L}{D} + \sum K_i\right)_{D_2} \frac{V_2^2}{2g} + \left(f\frac{L}{D} + \sum K_i\right)_{D_3} \frac{V_3^2}{2g}$$

Note: Be careful how you evaluate the transitions from one section to the next. In general, loss coefficients for transition sections are based on the velocity of the smaller section.

STUDENTS-HUB.com

Example: Given a pipe system as shown in the previous figure. The total pressure drop is $P_a - P_b = 150$ kPa and the elevation change is $Z_a - Z_b = -5$ m. Given the following data, determine the flow rate of water through the section.

Pipe	L (m)	D (cm)	e (mm)	e/D
1	100	8	0.24	0.003
2	150	6	0.12	0.02
3	80	4	0.2	0.005

The energy equation is written as

where hf is given by the sum of the total frictional losses for three pipe sections.

$$\frac{P_a - P_b}{\rho g} = \frac{V_b^2 - V_a^2}{2 g} + Z_b - Z_a + h_f - h_p$$

With no pump; hp is 0, $Z_b - Z_a =$ - 5 m and ht = 15.3 m for $\Delta P =$ 150 kPa

$$h_t = \frac{P_a - P_b}{\rho g} = \frac{150,000 \, N \,/ \,m^2}{9790 \, N \,/ \,m^2} = 15.3 \,m$$

Since the flow rate Q and thus velocity is the only remaining variable, the solution is easily obtained from a spreadsheet by assuming Q until $\Delta P = 150$ kPa.

Fluid			1	2	3
$\rho(kg/m^3) =$	1000	L(m)	100	150	80
$\nu(m^2/s) =$	1.02E-06	D(m) =	0.08	0.06	0.04
		$\epsilon(mm) =$	0.24	0.12	0.20
inlet & exit		ε/D=	0.003	0.002	0.005
dZ (m) =	-5				
Da(m) =	0.08	V(m/s)=	0.56	1.00	2.25
Db(m) =	0.04	Re =	44082.8	58777.1	88165.6
Assume		f=	0.02872	0.02591	0.03139
Q (m^3/s)=	0.00283	hf =	0.58	3.30	16.18
Va(m/s)=	0.56	Ki	0	0	0
Vb(m/s)=	2.25	hm=	0	0	0
dKE(m) =	0.24				
hf (net) =	20.08	hf(calc) =	0.58	3.30	16.18
	Actual	Calculated			
Pa - Pb (kPa)	150	150.00	Q(m^3/hr) =	10.17	

STUDENTS-HUB.com

Thus it is seen that a flow rate of 10.17 m³/hr produces the indicated head loss through each section and a net total $\Delta P = 150$ kPa.

A solution can also be obtained by writing all terms explicitly in terms of a single velocity, however, the algebra is quite complex (unless the flow is laminar), and an iterative solution is still required. All equations used to obtained the solution are the same as those presented in previous sections.

Parallel Pipe Systems

A flow rate Q_T enters the indicated parallel pipe system. The total flow splits and flows through 3 pipe sections, each with different diameters and lengths.

Two basic rules apply to parallel pipe systems;

- 1. The total flow entering the parallel section is equal to the sum of the flow rates through the individual sections,
- 2. The total pressure drop across the parallel section is equal to the pressure drop across each individual parallel segment.

Note that if a common junction is used for the start and end of the parallel section, the velocity and elevation change is also the same for each section. Thus, the flow rate through each section must be such that the frictional loss is the same for each and the sum of the flow rates equals the total flow.

For the special case of no kinetic or potential energy change across the sections, we obtain:

$$h_t = (h_f + h_m)_1 = (h_f + h_m)_2 = (h_f + h_m)_3$$

and

$$\mathbf{Q}_{\mathrm{T}} = \mathbf{Q}_1 + \mathbf{Q}_2 + \mathbf{Q}_3$$

STUDENTS-HUB.com

Again, the equation used for both the pipe friction and minor losses is the same as previously presented. The flow and pipe dimensions used for the previous example are now applied to the parallel circuit shown above.

Example: A parallel pipe section consists of three parallel pipe segments with the lengths and diameters shown below. The total pressure drop is 150 kPa and the parallel section has an elevation drop of 5 m. Neglecting minor losses and kinetic energy changes, determine the flow rate of water through each pipe section.

The solution is iterative and is again presented in a spreadsheet. The net friction head loss of 20.3 m now occurs across each of the three parallel sections.

Total Flow, Qt(m^3/hr) = 99.91

The strong effect of diameter can be seen with the smallest diameter having the lowest flow rate, even though it also has the shortest length of pipe.
